Path-properties of the tree-valued Fleming–Viot process

Andrej Depperschmidt[1], Andreas Greven[2] and Peter Pfaffelhuber[3]

December 24, 2012

Abstract

We consider the tree-valued Fleming–Viot process, $(\mathcal{X}_t)_{t\geq 0}$, with mutation and selection as studied in [DGP12]. This process models the stochastic evolution of the genealogies and (allelic) types under resampling, mutation and selection in the population currently alive in the limit of infinitely large populations. Genealogies and types are described by (isometry classes of) marked metric measure spaces. The long-time limit of the neutral tree-valued Fleming–Viot dynamics is an equilibrium given via the marked metric measure space associated with the Kingman coalescent.

In the present paper we pursue two closely linked goals. First, we show that two well-known properties of the Fleming–Viot genealogies at fixed time t arising from the properties of the dual, namely the Kingman coalescent, hold for the whole path. These properties are related to the geometry of the family tree close to its leaves. In particular we consider the number and the size of subfamilies whose individuals are not further than ε apart in the limit $\varepsilon \to 0$. Second, we answer two open questions about the sample paths of the tree-valued Fleming–Viot process. We show that for all $t > 0$ almost surely the marked metric measure space $\mathcal{X}_t$ has no atoms and admits a mark function. The latter property means that all individuals in the tree-valued Fleming–Viot process can uniquely be assigned a type. All main results are proven for the neutral case and then carried over to selective cases via Girsanov's formula giving absolute continuity.

Keywords and Phrases: Marked tree-valued Fleming–Viot process, path properties, selection, mutation, Kingman coalescent.

AMS 2000 Subject classification: Primary 60K35, 60J25; secondary 60J68, 92D10

1 Introduction and background

A frequently used model for stochastically evolving multitype populations is the Fleming–Viot diffusion. In the neutral case the corresponding genealogy at a fixed time t is described by the Kingman coalescent which was introduced some 30 years ago as the random genealogy relating the individuals of a population of large constant size in equilibrium [Kin82a, Kin82b].

As a genealogical tree with infinitely many leaves, the Kingman coalescent exhibits some distinct geometric properties. In particular, S. Evans studied the random tree as a metric space, where the distance of two leaves is given by the time to their most recent common ancestor [Eva00]. Using this picture, the Kingman coalescent close to its leaves has a nice shape: roughly speaking, in the limit $\varepsilon \to 0$, approximately $2/\varepsilon$ balls of radius 2ε are needed to cover the whole tree; see Section 4.2 in D. Aldous' review article [Ald99]. Equivalently, there are $2/\varepsilon$ families whose individuals have a common ancestor not further than ε in the past. Moreover, these $2/\varepsilon$ families have sizes of order ε. More precisely, the size of a typical family is exponential with parameter $2/\varepsilon$ (see [Ald99, eq (35)]), and the empirical distribution of the family sizes converges to this exponential distribution. However, these results have been proved only for the genealogy of a population at a fixed time.

In a series of papers of the authors, in part with A. Winter, [GPW09, DGP11, GPW12, DGP12] the Kingman coalescent was extended to a tree-valued process $(\mathcal{X}_t)_{t\geq 0}$, where $\mathcal{X}_t$ gives the genealogy of an evolving population at time t. The resulting process, the tree-valued Fleming–Viot process, is connected to the Fleming–Viot measure-valued diffusion, which describes the evolution of type-frequencies in a large (i.e. infinite) population of constant size. In the simplest case of neutral evolution all individuals have the same chance to produce viable offspring, i.e., the frequency of offspring of any subset of individuals is a martingale. However, biologically most interesting is the *selective case* where the evolutionary success of an individual depends on its (allelic) type and where also mutation (i.e. random changes in types) may occur. This case including mutation and selection was studied in [DGP12].

Goals: The construction of the tree-valued Fleming–Viot process allows to ask if the above mentioned properties of the geometry of the Kingman coalescent trees are almost sure path properties of the tree-valued Fleming-Viot process. Furthermore, while we gave a construction of the tree-valued Fleming–Viot process under neutrality in [GPW12] and under mutation and selection in [DGP12], some questions about path behavior remained open. We will carry over some (not all) of the geometric properties of the fixed random trees to the evolving paths of trees in Theorems 1 – 4 of this work.

In the next section, we explain in detail how we model *genealogical trees*. In order to formulate open questions let us briefly mention here that we use a *marked metric measure space (mmm-space)*, that is, a triple (U, r, μ) where (U, r) is a complete metric space describing genealogical distances between individuals and μ is a probability measure on the Borel-σ algebra of $U \times A$, where A is the set of possible (allelic) types. In particular, the tree-valued Fleming–Viot process $(\mathcal{X}_t)_{t\geq 0}$ takes values in the space of (continuous) paths in the space of mmm-spaces.

To state two open questions from earlier work, assume that $\mathcal{X}_t = (U_t, r_t, \mu_t)$ is the state of the tree-valued Fleming–Viot process at time $t \geq 0$. First, we ask if the measure μ_t has atoms for some $t > 0$. To understand what this means, recall that the state of the measure-valued Fleming–Viot process is purely atomic for all $t > 0$, almost surely. However, for the tree-valued state an atom in the measure $\mu_t \in \mathcal{M}_1(U_t \times A)$ implies that a family of individuals of positive μ_t-mass have zero genealogical distance. As we will see in Theorem 5, this is not possible, and the tree-valued Fleming–Viot process is non-atomic for all $t > 0$, almost surely. Second, we ask if every individual in U_t can uniquely be assigned a type which is of course the case for the Moran model, but does not automatically carry over to the (infinite population) diffusion limit. This is the case iff the support of μ_t is given by $\{(u, \kappa_t(u)) : u \in U_t\}$ for a function $\kappa_t : U_t \to A$. In Theorem 6, we will see that this is indeed the case and every individual can be assigned a type for all $t > 0$, almost surely.

Methods: Since the tree-valued Fleming–Viot process was constructed using a well-posed martingale problem, we will frequently use martingale techniques in our proofs. This allows to study the *sample Laplace-transform* for the distance of two points of the tree as a semi-martingale. In addition, population models have specific features that will also be useful. For example all individuals have unique ancestors even though not all individuals have descendants and if an individual has a descendant, she might as well have many. This simple structure can be used for finite population models (e.g. the Moran model) or the tree-valued Fleming–Viot process, since this infinite model arises as a large-population limit from finite Moran models (for the neutral case see [GPW12, Theorem 2] and for the selective case [DGP12, Theorem 3]) to derive properties of the family structure.

An important point of the proofs is that we can transfer properties from the neutral case since for most forms of selection (which are determined by the interacting fitness functions, which gives the dependence of the offspring distribution depends on the allelic type), the resulting process is *absolutely continuous* to the *neutral case* (which comes with no dependency between allelic type and offspring distribution) via a *Girsanov transform*.

Outline: The paper is organized as follows: In Section 2 we recall the definition of the state space of the tree-valued Fleming–Viot process, its construction by a well-posed martingale problem and some of its properties. In Section 3, we give our main results. Theorem 1 states that the law of large numbers for the number of ancestors of Kingman's coalescent holds along the whole path of the tree-valued Fleming–Viot process. Moreover, we discover a Brownian motion within the tree-valued Fleming–Viot process based on the fluctuations of the number of ancestors; see Theorem 2. Another law of large numbers is obtained for a statistic concerning the family sizes and we make a big step towards this result in Theorem 3. Another Brownian Motion is discovered within the tree-valued Fleming–Viot process based on family sizes in Theorem 4. Finally we show the non-atomicity along the path in Theorem 5 and obtain existence of a mark function in Theorem 6.

In Section 4 we prove Theorem 1 and after some preparatory moment computations in Section 5, we give in the subsequent sections the remaining proofs of the main results. We note that various proofs have been carried out using Mathematica and can be reproduced by the reader via the accompanying Mathematica-file.

2 The tree-valued Fleming–Viot process

In this section, we recall the tree-valued Fleming–Viot process given as the unique solution of a *martingale problem* on the space of *marked metric measure spaces*. The material presented here is a condensed version of results from [GPW09, DGP11, GPW12] and [DGP12]. We only recall notions needed to follow our arguments in the present paper. Let us fix some notation first.

Notation 2.1.
For a Polish space E the set of all bounded measurable functions is denoted by $\mathcal{B}(E)$,

its subset containing the bounded and continuous functions by $\mathcal{C}_b(E)$, the set of càdlàg function $I \subseteq \mathbb{R} \to E$ by $\mathcal{D}_E(I)$ (which is equipped with the Skorohod topology) and the subset of continuous functions by $\mathcal{C}_E(I)$. The set of probability measures on (the Borel σ-algebra of) E is denoted by $\mathcal{M}_1(E)$ and $\Rightarrow$ denotes either weak convergence of probability measures or convergence in distribution of random variables. If $\phi : E \to E'$ for some Polish space E' then the image measure of $\mu \in \mathcal{M}_1(E)$ under ϕ is denoted by $\phi_*\mu$. For functions $\lambda \mapsto a_\lambda$ and $\lambda \mapsto b_\lambda$, we write $a_\lambda \lesssim b_\lambda$ if there is $C > 0$ such that $a_\lambda \leq C b_\lambda$ uniformly for all λ. Furthermore for $\lambda_0 \in \mathbb{R} \cup \{\pm\infty\}$ we write $a_\lambda \overset{\lambda\to\lambda_0}{\approx} b_\lambda$ if a_λ and b_λ are asymptotically equivalent as $\lambda \to \lambda_0$, i.e. if $a_\lambda / b_\lambda \to 1$ as $\lambda \to \lambda_0$. For product spaces $E_1 \times E_2 \times \ldots$ we denote the projection operators by $\pi_{E_1}, \pi_{E_2}, \ldots$. When there is no chance of ambiguity we use the shorter notation $\pi_1, \pi_2, \ldots$.

2.1 The state space: genealogies as marked metric measure spaces

Throughout, we fix a *compact metric space* A which we refer to as the *(allelic) type space*. An *A-marked (ultra-)metric measure space*, abbreviated as A-mmm space or just mmm-space in the following, is a triple (U, r, μ), where (U, r) is an ultra-metric space and $\mu \in \mathcal{M}_1(U \times A)$ is a probability measure on $U \times A$.

The state space of the tree-valued Fleming–Viot process is

$$\mathbb{U}_A := \big\{\overline{(U, r, \mu)} : (U, r, \mu) \text{ is } A\text{-mmm space}\big\}, \tag{2.1}$$

where $\overline{(U, r, \mu)}$ is the equivalence class of the A-mmm space (U, r, μ), and two mmm-spaces (U_1, r_1, μ_1) and (U_2, r_2, μ_2) are called *equivalent* if there exists an isometry (here supp of a measure denotes its support)

$$\varphi : \operatorname{supp}\big(\pi_{U_1 *}\mu_1\big) \to \operatorname{supp}\big(\pi_{U_2 *}\mu_2\big) \tag{2.2}$$

with $(\varphi, id)_*\mu_1 = \mu_2$. The subspace of compact mmm-spaces

$$\mathbb{U}_{A,c} := \big\{\overline{(U, r, \mu)} \in \mathbb{U}_A : (U, r) \text{ compact}\big\} \subsetneq \mathbb{U}_A \tag{2.3}$$

will play an important role.

Remark 2.2 (Interpretation of equivalent marked metric measure spaces).
1. In our presentation, only *ultra*-metric spaces (U, r) will appear. The reason is that we only consider stochastic processes whose state at time t describes the genealogy of the population alive at time t, which makes r an ultra-metric.

2. There are several reasons why we consider equivalence classes of marked metric spaces instead of the marked metric spaces themselves. The most important is that we view a genealogical tree as a metric space on its set of leaves. Since in population genetic models the individuals are regarded as exchangeable (at least among individuals carrying the same allelic type), reordering of leaves does not change (in this view) the tree.

In order to construct a stochastic process with càdlàg paths and state space $\mathbb{U}_A$, we have to introduce a topology. To this end, we need to introduce test functions with domain $\mathbb{U}_A$.

Definition 2.3 (Polynomials).
We set $\mathbb{R}^{\binom{\mathbb{N}}{2}} := \{\underline{\underline{r}} := (r_{ij})_{1\leq i<j} : r_{ij} \in \mathbb{R}\}$. A function $\Phi : \mathbb{U}_A \to \mathbb{R}$ is a polynomial*, if there is a measurable function $\phi : \mathbb{R}^{\binom{\mathbb{N}}{2}} \times A^{\mathbb{N}} \to \mathbb{R}$ depending only on finitely many coordinates such that*

$$\begin{aligned}\Phi\big(\overline{(U, r, \mu)}\big) &:= \Phi^\phi\big(\overline{(U, r, \mu)}\big) \\ &:= \langle \mu^{\otimes\mathbb{N}}, \phi \rangle := \int \mu^{\otimes\mathbb{N}}(d\underline{u}, d\underline{a})\, \phi\big(r(u_i, u_j)_{1\leq i<j}, (a_i)_{i\geq 1}\big),\end{aligned} \tag{2.4}$$

where $\mu^{\otimes\mathbb{N}}$ is the infinite product measure, i.e. the law of a sequence sampled independently with sampling measure μ.

Let us remark that functions of the form (2.4) are actually monomials. However, products and sums of such monomials are again monomials, and hence we may in fact speak of polynomials; cf. the example below.

Remark 2.4 (Interpretation of polynomials)**.**
Assume that ϕ only depends on the first $\binom{n}{2}$ coordinates in $r(u_i,u_j)_{1\le i<j}$ and the first n in $(a_i)_{i\ge 1}$. Then, we view a function of the form (2.4) as taking a sample of size n according to μ from the population, observing the value under ϕ of this sample and then taking the μ-sample mean over the population.

Example 2.5 (Some functions of the form (2.4))**.**
Some functions of the form (2.4) will appear frequently in this paper, for example $\underline{\underline{r}} \mapsto \phi(\underline{\underline{r}}) := \psi_\lambda^{12}(\underline{\underline{r}}) := e^{-\lambda r_{12}}$,

$$\Psi_\lambda^{12}\big(\overline{(U,r,\mu)}\big) := \langle \mu^{\otimes\mathbb{N}}, \psi_\lambda^{12}\rangle = \int (\pi_{1*}\mu)^{\otimes 2}(du_1,du_2)e^{-\lambda r(u_1,u_2)}. \tag{2.5}$$

This function arises from sampling two leaves, u_1 and u_2, from the genealogy (U,r) according to $\pi_{1*}\mu$ and averaging over the test function $e^{-\lambda r(u_1,u_2)}$ of this sample. Then $(\Psi^{12})^2$ is again of the form (2.4) and

$$(\Psi_\lambda^{12})^2\big(\overline{(U,r,\mu)}\big) = \int ((\pi_1)_*\mu)^{\otimes 4}(du_1,\dots,du_4)e^{-\lambda(r(u_1,u_2)+r(u_3,u_4))}. \tag{2.6}$$

Another function that will be used and which also depends on types is given by

$$\widehat{\Psi}_\lambda^{12}\big(\overline{(U,r,\mu)}\big) := \int \mu^{\otimes 2}(du_1,du_2,da_1,da_2)\mathbb{1}_{\{a_1=a_2\}}e^{-\lambda r(u_1,u_2)}. \tag{2.7}$$

In this function u_1 and u_2 contribute to the integral only if their types, a_1 and a_2 agree.

Since we use polynomials as the domain of the generator for the tree-valued Fleming–Viot process, we need to restrict this class to smooth functions.

Definition 2.6 (Smooth polynomials)**.**
We denote by

$$\Pi^1 := \Big\{\Phi^\phi \text{ as in (2.4)} : \phi \text{ bounded, measurable and for all } \underline{a}\in A^{\mathbb{N}},\ \phi(\cdot,\underline{a})\in \mathcal{C}_b^1\big(\mathbb{R}^{\binom{\mathbb{N}}{2}}\big)\Big\} \tag{2.8}$$

the set of smooth (in the first coordinate) polynomials*. Furthermore we denote by Π_n^1 the subset of Π^1 consisting of all Φ^ϕ for which $\phi(\underline{\underline{r}},\underline{a})$ depends at most on the first $\binom{n}{2}$ coordinates of $\underline{\underline{r}}$ and the first n of $\underline{a}$ and hence have degree at most n.*

Definition 2.7 (Marked Gromov-weak topology)**.**
The marked Gromov-weak topology *on $\mathbb{U}_A$ is the coarsest topology such that all $\Phi^\phi\in\Pi^1$ with (in both variables) continuous ϕ are continuous.*

The following is from [DGP11, Theorems 2 and 5]

Proposition 2.8 (Some topological facts about $\mathbb{U}$)**.**
The following properties hold:

1. *The space $\mathbb{U}_A$ equipped with the marked Gromov-weak topology is Polish.*

2. *The set Π^1 is a convergence determining algebra of functions, i.e. for random $\mathbb{U}_A$-valued variables $X, X_1, X_2, \dots$ we have*

$$X_n \xRightarrow{n\to\infty} X \quad \textit{iff} \quad \mathbf{E}[\Phi(X_n)] \xrightarrow{n\to\infty} \mathbf{E}[\Phi(X)] \ \textit{ for all } \ \Phi\in\Pi^1. \tag{2.9}$$

2.2 Construction of the tree-valued FV-process

The tree-valued Fleming–Viot process will be defined via a well-posed martingale problem. Let us briefly recall the concept of a martingale problem.

Definition 2.9 (Martingale problem).
Let E be a Polish space, $\mathbf{P}_0 \in \mathcal{M}_1(E)$, $\mathcal{F} \subseteq \mathcal{B}(E)$ and Ω a linear operator on $\mathcal{B}(E)$ with domain $\mathcal{F}$. The law $\mathbf{P}$ of an E-valued stochastic process $\mathcal{X} = (X_t)_{t\geq 0}$ is a solution of the $(\mathbf{P}_0, \Omega, \mathcal{F})$-martingale problem *if X_0 has distribution $\mathbf{P}_0$, $\mathcal{X}$ has paths in the space $\mathcal{D}_E([0,\infty))$, almost surely, and for all $F \in \mathcal{F}$,*

$$\Big(F(X_t) - \int_0^t \Omega F(X_s)ds\Big)_{t\geq 0} \tag{2.10}$$

is a $\mathbf{P}$-martingale with respect to the canonical filtration. The $(\mathbf{P}_0, \Omega, \mathcal{F})$-martingale problem is said to be well-posed *if there is a unique solution $\mathbf{P}$.*

Let us first specify the *generator* of the tree-valued Fleming–Viot process. It is a *linear operator with domain* Π^1, given by

$$\Omega := \Omega^{\text{grow}} + \Omega^{\text{res}} + \Omega^{\text{mut}} + \Omega^{\text{sel}}. \tag{2.11}$$

Here, for $\Phi = \Phi^\phi \in \Pi^1_n$, the linear operators $\Omega^{\text{grow}}, \Omega^{\text{res}}, \Omega^{\text{mut}}, \Omega^{\text{sel}}$ are defined as follows:

1. We define the *growth operator* by

   $$\Omega^{\text{grow}}\Phi\big(\overline{(U,r,\mu)}\big) := \big\langle \mu^{\otimes\mathbb{N}}, \langle \nabla_{\underline{\underline{r}}}\phi, 2\rangle\big\rangle, \tag{2.12}$$

   with

   $$\langle \nabla_{\underline{\underline{r}}}\phi, 2\rangle := 2\sum_{1\leq i<j} \frac{\partial\phi}{\partial r_{ij}}(\underline{\underline{r}}, \underline{u}). \tag{2.13}$$

2. We define the *resampling operator* by

   $$\Omega^{\text{res}}\Phi\big(\overline{(U,r,\mu)}\big) := \frac{1}{2}\sum_{k,\ell=1}^{n} \langle \mu^{\otimes\mathbb{N}}, \phi\circ\theta_{k,\ell} - \phi\rangle, \tag{2.14}$$

   with $\theta_{k,\ell}(\underline{\underline{r}}, \underline{a}) = (\tilde{\underline{\underline{r}}}, \tilde{\underline{a}})$, where

   $$\tilde{\underline{\underline{r}}}_{ij} := \begin{cases} r_{ij}, & \text{if } i,j \neq \ell, \\ r_{i\wedge k, i\vee k}, & \text{if } j = \ell, \\ r_{j\wedge k, j\vee k}, & \text{if } i = \ell, \end{cases} \quad \text{and} \quad \tilde{\underline{a}}_i := \begin{cases} a_i, & i\neq \ell, \\ a_k, & i = \ell. \end{cases} \tag{2.15}$$

3. For the *mutation operator*, let $\vartheta \geq 0$ and $\beta(\cdot,\cdot)$ be a Markov transition kernel from A to the *Borel sets* of A and set

   $$\Omega^{\text{mut}}\Phi\big(\overline{(U,r,\mu)}\big) := \vartheta\cdot\sum_{k=1}^{n} \langle \mu^{\otimes\mathbb{N}}, B_k\phi\rangle, \tag{2.16}$$

   where

   $$\begin{aligned} B_k\phi &:= \beta_k\phi - \phi, \\ (\beta_k\phi)(\underline{\underline{r}}, \underline{a}) &:= \int \phi(\underline{\underline{r}}, \underline{a}_k^b)\beta(a_k, db), \\ \underline{a}_k^b &:= (a_1, \dots, a_{k-1}, b, a_{k+1}, \dots). \end{aligned} \tag{2.17}$$

   We say that mutation has a parent-independent component if $\beta(\cdot,\cdot)$ is of the form

   $$\beta(u, dv) = z\bar{\beta}(dv) + (1-z)\widetilde{\beta}(u, dv) \tag{2.18}$$

   for some $z \in (0,1]$, $\bar{\beta} \in \mathcal{M}_1(A)$ and a probability transition kernel $\widetilde{\beta}$ on A.

4. For *selection*, consider the *fitness function*

$$\chi' : A \times A \times \mathbb{R}_+ \to [0,1] \tag{2.19}$$

with $\chi'(a,b,r) = \chi'(b,a,r)$ for all $a, b \in A, r \in \mathbb{R}_+$. We require that $\chi' \in \overline{\mathcal{C}}^{0,0,1}(A \times A \times \mathbb{R}_+)$, i.e. χ' is continuous and continuously differentiable with respect to its third coordinate. Then, with $\alpha \geq 0$ (the selection intensity) and

$$\chi'_{k,l}(\underline{\underline{r}}, \underline{a}) = \chi'(a_k, a_l, r_{k\wedge l, k\vee l}) \tag{2.20}$$

we set

$$\Omega^{\mathrm{sel}}\Phi\big(\overline{(U,r,\mu)}\big) \coloneqq \alpha \cdot \sum_{k=1}^{n} \langle \mu^{\otimes\mathbb{N}}, \phi \cdot \chi'_{k,n+1} - \phi \cdot \chi'_{n+1,n+2}\rangle. \tag{2.21}$$

If $\chi'(a,b,r)$ does not depend on r, and if there is $\chi : A \to [0,1]$ such that

$$\chi'(a,b,r) = \chi(a) + \chi(b), \tag{2.22}$$

we say that selection is additive and conclude that with

$$\chi_k(\underline{\underline{r}}, \underline{a}) = \chi(a_k), \tag{2.23}$$

we have

$$\Omega^{\mathrm{sel}}\Phi\big(\overline{(U,r,\mu)}\big) := \alpha \cdot \sum_{k=1}^{n} \langle \mu^{\otimes\mathbb{N}}, \phi \cdot \chi_k - \phi \cdot \chi_{n+1}\rangle. \tag{2.24}$$

Remark 2.10 (Interpretation of generator terms)**.**
The growth, resampling, mutation and selection generator terms are interpreted as follows:

1. *Growth:* When time passes, the genealogical distance of any pair of individuals gets larger. Precisely, the time to the most recent common ancestor (MRCA) for any pair grows at speed 2 because every single branch grows at speed 1.

2. *Resampling:* The term $\langle \mu^{\otimes\mathbb{N}}, \phi \circ \theta_{k,\ell} - \phi\rangle$ describes the action of an event where an offspring of individual k replaces individual ℓ in the sample corresponding to the polynomial Φ^{ϕ}. This term is analogous to the measure-valued case (see e.g. [EK93, eq. (3.21)]), but acts on both, the genealogy and the types.

3. *Mutation:* It is important to note that mutation only affects types, but not genealogical distances. Hence, the mutation operator agrees with the measure-valued case (see e.g. [EK93, eq. (3.16)]). Note that here we consider only jump operators B.

4. *Selection:* This term is best understood when considering a finite population. Consider for simplicity the case of additive selection (i.e. (2.22) holds) in particular covering haploid models. Here, the offspring of an individual of type a replaces some randomly chosen individual at rate $\alpha\chi(a)$ due to selection. In the large population limit, we only consider a sample of n individuals and this sample changes only if some offspring of an individual outside the sample, e.g. the $(n+1)$st individual by exchangeability, replaces an individual within the sample, the kth say, due to selection. After this selection event, the fitness of the kth individuals is $\chi(a)$ which is also seen from the generator term. In the case of selection acting on diploids, the situation is similar, but one has to build diploids from haploids first and then apply the fitness function.

In [GPW12, DGP12] the tree-valued Fleming–Viot processes were constructed via well-posed martingale problems. The following proposition summarizes Theorems 1, 2 and 4 from [DGP12].

Proposition 2.11 (Tree-valued Fleming–Viot process)**.**
For $\mathbf{P}_0 \in \mathcal{M}_1(\mathbb{U})$ *the* $(\mathbf{P}_0, \Omega, \Pi^1)$*-martingale problem is well-posed. Its solution* $\mathcal{X} = (X_t)_{t\geq 0}$ *defines a Feller semigroup, i.e.* $X_0 \mapsto \mathbf{E}[f(X_t)|X_0]$ *is continuous for all* $f \in \mathcal{C}_b(\mathbb{U})$*, and hence,* $\mathcal{X}$ *is a strong Markov process.*

Furthermore, the process $\mathcal{X}$ *satisfies the following properties:*

1. $\mathbf{P}(t \mapsto X_t \text{ is continuous}) = 1$.
2. $\mathbf{P}(X_t \in \mathbb{U}_{A,c} \text{ for all } t > 0) = 1$.
3. *Let* $\Phi = \Phi^\phi \in \Pi^1_n$ *such that* ϕ *is symmetric under permutations. Then, the quadratic variation of the semi-martingale* $\Phi(\mathcal{X}) \coloneqq (\Phi(X_t))_{t\geq 0}$ *is given by*
$$[\Phi(\mathcal{X})]_t = \int_0^t \big\langle \mu_s, \big(\rho_s - \langle \mu_s, \rho_s\rangle\big)^2\big\rangle \, ds, \tag{2.25}$$
$$\rho_s(u_1) \coloneqq \int \mu_s^{\otimes\mathbb{N}}(d(u_2, u_3, \dots))\phi((r_s(u_i, u_j))_{1\leq i<j}). \tag{2.26}$$
4. *Let* $\mathbf{P}_\alpha$ *be the distribution of* $\mathcal{X}$ *with selection intensity* α*. Then, for all* $\alpha, \alpha' \geq 0$*, the laws* $\mathbf{P}_\alpha$ *and* $\mathbf{P}_{\alpha'}$ *are absolutely continuous with respect to each other.*
5. *If either (i)* $\alpha = 0$ *and the process with generator* Ω^{mut} *has a unique equilibrium or (ii)* $\alpha \geq 0$ *and mutation has a parent-independent component, then the process* $\mathcal{X}$ *is ergodic. That is, there is an* $\mathbb{U}_{A,c}$*-valued random variable* X_∞*, depending on the model parameters but not the initial law, such that* $X_t \xRightarrow{t\to\infty} X_\infty$*.*

Definition 2.12 (Tree-valued Fleming–Viot process and marked Kingman measure tree)**.**
Using the same notation as in Proposition 2.11, we call the process $\mathcal{X}$ *the* tree-valued Fleming–Viot process *and in the case* $\alpha = 0$ *its ergodic limit*
$$X_\infty = \overline{(U_\infty, r_\infty, \mu_\infty)} \tag{2.27}$$
is called Kingman marked measure tree*.*

Remark 2.13 (The Kingman measure tree)**.**
The random variable X_∞ arises from the marked ultrametric measure space which is associated with the partition-valued entrance law of the Kingman coalescent [GPW09].

Example 2.14 (The quadratic variation of $(\Psi^{12}_\lambda(X_t))_{t\geq 0}$)**.**
In some of the proofs, we will need to compute the quadratic variation of $\Phi(\mathcal{X}) \coloneqq (\Phi(X_t))_{t\geq 0}$ for specific $\Phi \in \Pi^1$ via (2.25) explicitly. For Ψ^{12}_λ as in Example 2.5, we have by (2.25)
$$[\Psi^{12}_\lambda(\mathcal{X})]_t = \int_0^t \big(\Psi^{12,23}_\lambda(X_s) - \Psi^{12,34}_\lambda(X_s)\big)\, ds, \tag{2.28}$$
with (cf. Definition 5.6)
$$\Psi^{ij,kl}_\lambda\big(\overline{(U, r, \mu)}\big) = \big\langle \mu^{\otimes\mathbb{N}}, e^{-\lambda(r(u_i,u_j)+r(u_k,u_l))}\big\rangle, \qquad i, j, k, l = 1, 2, \dots \tag{2.29}$$

3 Results

Our main goal is to establish almost sure properties of the paths of the tree-valued Fleming–Viot process, beyond continuity of paths and the property that the states are compact marked metric measure space for every $t > 0$, almost surely. We start by studying the geometry of the marked metric measure tree at time t of the tree-valued Fleming–Viot process. First we recall in Section 3.1 some well-known facts concerning the geometry of the Kingman coalescent and then extend them in Section 3.2 to the tree-valued Fleming–Viot process. In Section 3.3 we take advantage of our results and techniques and state some further path properties of the tree-valued Fleming–Viot process answering two open questions.

3.1 Geometric properties of the Kingman coalescent near the leaves

We focus on the equilibrium marked metric measure X_∞ introduced in Proposition 2.11.5, but for most assertions in this subsection we can ignore the marks (i.e. think of A consisting of only one element). Since the introduction of the partition-valued Kingman coalescent in [Kin82a], this random tree has been studied extensively for instance in [Ald99] and [Eva00]. In our present formalism (using metric measure spaces), X_∞ appeared first in [GPW09]. In this section, we mostly reformulate known results, but also add a new one in Proposition 3.6.

The Kingman measure tree, X_∞, arises from the partition-valued Kingman coalescent, but can also be realized as a discrete graph tree using the following construction. Let $S_2, S_3, \dots$ be independent exponentially distributed random variables with parameter 1. Starting with two lines from the root the tree stays with these two lines for time $S_2/\binom{2}{2}$. At time S_2 one of the two lines chosen at random splits in two, such that three lines are present. In general after the jump from $k-1$ to k lines the tree stays with that k lines for a period of time $S_k/\binom{k}{2}$ and then one of the k lines chosen at random splits, such that there are $k+1$ lines. The total tree height is thus T_1, where $T_n \coloneqq S_{n+1}/\binom{n+1}{2} + S_{n+2}/\binom{n+2}{2} + \cdots$, i.e. T_n is the time it takes the coalescent to go from n to infinitely many lines. The time of the root is called the time of the most recent common ancestor (MRCA) and T is the present time of the population. Before time T, we consider the uniform distribution on the branches and construct a tree-indexed Markov process, by using a collection of independent mutation processes as follows. Start with an equilibrium value of the mutation processes at the root up to the next splitting time where we continue with two independent mutation processes both starting from the type in the vertex, etc. Running from the root to the leaves and letting time approach T we finally obtain X_∞.

At time ε (counted from the top of the tree, for $\varepsilon < T_1$), a random number N_ε of lines are present. Equivalently, N_ε is the minimal number of 2ε-balls needed to cover (the leaves of) the random tree X_∞. It is a well-known fact using de Finetti's Theorem that the frequency of the family descending from every of the N_ε lines can be defined for all $\varepsilon > 0$. In addition, these frequencies are distributed as the spacings between N_ε on $[0, 1]$ uniformly distributed random variables [Pyk65].

From these considerations several results on the geometry of X_∞ near the leaves can be derived. We briefly recall and extend some of them and reprove them later in our setting. Roughly we will show that there are $2/\varepsilon \pm \mathcal{O}(1/\sqrt{\varepsilon})$-many families in which the genealogical distance between the individuals is at most 2ε. Furthermore, each of the families has mass of order ε, as $\varepsilon \to 0$. More precisely, the distribution of (by ε rescaled) family sizes is exponential with rate 2.

We split the above picture in two parts. First we study the number of families and then their size in both cases looking at a LLN and then at a CLT. We begin with a law of large numbers and a central limit theorem for N_ε (see [Ald99, eq. (35)]). Our proofs are given in Sections 4.2 and 4.3.

Proposition 3.1 (LLN for the number of balls to cover X_∞)**.**
Let $X_\infty = \overline{(U_\infty, r_\infty, \mu_\infty)}$ be the Kingman measure tree. Moreover, let N_ε be the (minimal) number of 2ε-balls needed to cover (U_∞, r_∞). Then

$$\varepsilon N_\varepsilon \xrightarrow{\varepsilon\to 0} 2, \quad \textit{almost surely.} \tag{3.1}$$

Proposition 3.2 (CLT for the number of balls to cover X_∞)**.**
With the same notation as in Proposition 3.1 and $Z \sim N(0,1)$,

$$\frac{N_\varepsilon - 2/\varepsilon}{\sqrt{2/(3\varepsilon)}} \overset{\varepsilon\to 0}{\Longrightarrow} Z \tag{3.2}$$

and

$$\mathbb{E}\Big[\Big(\frac{N_\varepsilon - 2/\varepsilon}{\sqrt{2/(3\varepsilon)}}\Big)^2\Big] \xrightarrow{\varepsilon\to 0} 1, \qquad \mathbb{E}\Big[\Big(\frac{N_\varepsilon - 2/\varepsilon}{\sqrt{2/(3\varepsilon)}}\Big)^4\Big] \xrightarrow{\varepsilon\to 0} 1. \tag{3.3}$$

We now come to the *family structure* of $X_\infty = \overline{(U_\infty, r_\infty, \mu_\infty)}$ close to the leaves. For $\varepsilon > 0$, we define $B_{2\varepsilon}(1), \dots, B_{2\varepsilon}(N_\varepsilon) \subseteq U_\infty$ as the disjoint balls of radius 2ε that cover U_∞ and the corresponding frequencies by

$$F_i(2\varepsilon) := \mu_\infty(B_{2\varepsilon}(i)), \; i = 1, \dots, N_\varepsilon. \tag{3.4}$$

This can be viewed as the frequency vector of a sequence of exchangeable random variables and we can ask for the law of the empirical distribution of the scaled masses in the limit $\varepsilon \to 0$, where the underlying sequence, even if scaled, becomes i.i.d. and we should get the scaled law of a single scaled F_i. It turns out, a first step (cf. Remark 3.5) is to see that the following law of large numbers holds, the proof of which (together with the proof of Lemma 3.4) appears in Section 6.

Proposition 3.3 (Asymptotics of ball masses near the leaves)**.**
For $F_i(2\varepsilon)$ as above,

$$\frac{1}{\varepsilon}\sum_{i=1}^{N_\varepsilon} F_i(2\varepsilon)^2 \xrightarrow{\varepsilon\to 0} 1 \tag{3.5}$$

almost surely.

The classical proof of Proposition 3.3 uses the fact that the random vector $\big(F_1(2\varepsilon), \dots, F_{N_\varepsilon}(2\varepsilon)\big)$ has the same distribution as the vector of spacings between N_ε random variables uniformly distributed on $[0,1]$. This vector in turn has the same distribution as $\big(Y_1/(\sum_{i=1}^{N_\varepsilon} Y_i), \dots, Y_{N_\varepsilon}/(\sum_{i=1}^{N_\varepsilon} Y_i)\big)$, where $Y_1, Y_2, \dots$ are i.i.d. $\text{Exp}(1)$ random variables. Then, using a moment computation, (3.5) can be proved. For details we refer to [Eva00, Section 2]). We will use a different route for which we need the following auxiliary Tauberian result.

Lemma 3.4 (Reformulation)**.**
The assertions

$$\frac{1}{\varepsilon}\sum_{i=1}^{N_\varepsilon} F_i(2\varepsilon)^2 \xrightarrow{\varepsilon\to 0} 1, \quad \textit{a.s.} \tag{3.6}$$

$$(\lambda+1)\Psi_\lambda^{12}(X_\infty) \xrightarrow{\lambda\to\infty} 1 \;\; \textit{a.s.} \tag{3.7}$$

with Ψ_λ^{12} *from Example 2.5 are equivalent. Moreover, the equivalence remains true if we replace* ε *by* $\varepsilon_n \downarrow 0$*,* λ *by* $\lambda_n \uparrow \infty$ *with* $\varepsilon_n\lambda_n = 1$ *and let* $n \to \infty$*.*

Remark 3.5 (Refinements of Proposition 3.3)**.**
Actually, [Ald99] contains refinements of Proposition 3.3.

1. In equation (35) of [Ald99] it is claimed that (correcting a typo in Aldous' equation)

$$\sup_{0\le x<\infty} \left| \frac{\varepsilon}{2} \sum_{i=1}^{N_\varepsilon} \mathbb{1}_{\{F_i(2\varepsilon)<\varepsilon x\}} - (1-e^{-2x}) \right| \xrightarrow{\varepsilon\to 0} 0 \ \text{ a.s.} \tag{3.8}$$

   This means that the Kingman coalescent at distance ε from the tree top consists of approximately $2/\varepsilon$ families, and the size of each family has an exponentially distributed size with expectation $\varepsilon/2$ or the empirical measure of the family sizes converges weakly to the exponential distribution with mean 2, denoted by $\mathrm{Exp}(2)$.

   In order to show this assertion from moments of $(F_i(2\varepsilon))_{i=1,\dots,N_\varepsilon}$, it is necessary and sufficient that for $k = 1, 2, \dots$

$$\frac{1}{\varepsilon^{k-1}} \sum_{i=1}^{N_\varepsilon} (F_i(2\varepsilon))^k \xrightarrow{\varepsilon\to 0} 2^{-(k-1)} k! \quad \text{a.s.} \tag{3.9}$$

   The sufficiency follows since the moment problem for the exponential distribution is well posed, while for the necessity, we assume that (3.8) holds, and then one concludes

$$\begin{aligned} \frac{1}{\varepsilon} \sum_{i=1}^{N_\varepsilon} F_i(2\varepsilon)^2 &= \frac{2}{\varepsilon} \sum_{i=1}^{N_\varepsilon} \int_0^{F_i(2\varepsilon)} x\,dx = \frac{2}{\varepsilon} \sum_{i=1}^{N_\varepsilon} \int_0^\infty \mathbb{1}_{\{\varepsilon x \le F_i(2\varepsilon)\}} x\,dx \\ &\overset{\varepsilon\to 0}{\approx} \int_0^\infty 4xe^{-2x}\,dx = 1 \end{aligned} \tag{3.10}$$

   as well as, for $k \ge 2$,

$$\begin{aligned} \frac{1}{\varepsilon^{k-1}} \sum_{i=1}^{N_\varepsilon} F_i(2\varepsilon)^k &= \frac{k}{\varepsilon^{k-1}} \sum_{i=1}^{N_\varepsilon} \int_0^{F_i(2\varepsilon)} x^{k-1}\,dx = k\varepsilon \sum_{i=1}^{N_\varepsilon} \int_0^\infty \mathbb{1}_{\{\varepsilon x \le F_i(2\varepsilon)\}} x^{k-1}\,dx \\ &\overset{\varepsilon\to 0}{\approx} \int_0^\infty 2kx^{k-1}e^{-2x}\,dx = 2^{-(k-1)}k!. \end{aligned} \tag{3.11}$$

2. The statement (3.8) raises the issue to determine the fluctuations in that LLN, i.e. to derive a CLT. Here, [Ald99, (36)] states that

$$\sqrt{\frac{2}{\varepsilon}} \Big(\frac{\varepsilon}{2} \sum_{i=1}^{N_\varepsilon} \mathbb{1}_{\{F_i(2\varepsilon)<\varepsilon x\}} - (1-e^{-2x}) \Big)_{x\ge 0} \overset{\varepsilon\to 0}{\Longrightarrow} \big(B^0_{1-e^{-2x}} + \tfrac{1}{\sqrt{6}}(1-e^{-2x})Z \big)_{x\ge 0}, \tag{3.12}$$

   where $(B_t^0)_{0\le t\le 1}$ is a Brownian bridge. Another, for us more suitable formulation is to consider the sum multiplied by N_ε^{-1} instead of $\varepsilon/2$, so that Z disappears on the right hand side. In this case one would consider the fluctuations of the empirical measure of masses of the $B(2\varepsilon)$-balls that cover the Kingman coalescent tree.

We have so far investigated the behavior on top of the tree close to the leaves looking at the family sizes with respect to fixed degree 2ε of kinship for $\varepsilon \to 0$. This picture can be refined by obtaining fluctuation results in (3.5) (or (3.7)). We obtain a partial result by considering a degree of kinship ε/t for t varying in $\mathbb{R}_+$ and letting $\varepsilon \to 0$. This gives a *profile* of the *family sizes* of varying degrees of kinship and their correlation structure close to the leaves, if we view the scaling limit as a function of $t > 0$. This profile should be the deterministic flow of distributions $\{\text{Exp}(2/t) : t > 0\}$ which are the limits of

$$\frac{1}{N_{\varepsilon/t}} \left(\sum_{i=1}^{N_{\varepsilon/t}} \delta_{\varepsilon^{-1} F_i(2\varepsilon/t)} \right). \tag{3.13}$$

Again we consider the Laplace transform given through Ψ^{12}_λ and obtain the following fluctuation result – proved in Section 6.4.

Proposition 3.6 (Fluctuations of scaled small masses in small balls)**.**
Let X_∞ be the Kingman measure tree. Define the process $\mathcal{Z}^\lambda := (Z^\lambda_t)_{t\geq 0}$ by

$$Z^\lambda_t := \sqrt{\lambda}\big((\lambda t + 1)\Psi^{12}_{\lambda t}(X_\infty) - 1\big). \tag{3.14}$$

Then every sequence $(Z^{\lambda_n})_{n\geq 0}$ with $\lambda_n \to \infty$ has a convergent subsequence $(\lambda'_n)_{n\geq 0}$ with

$$\mathcal{Z}^{\lambda'_n} \xRightarrow{n\to\infty} \mathcal{Z}, \tag{3.15}$$

for some process $\mathcal{Z} := (Z_t)_{t>0}$ with continuous paths. Furthermore all limit points satisfy

$$\begin{aligned} \mathbf{E}[Z_t] &= 0, \\ \mathbf{Var}[Z_t] &= \frac{2}{t}, \\ \mathbf{Cov}(Z_s, Z_t) &= \frac{4st}{(s+t)^3}, \\ \mathbf{E}[Z_t^3] &= 0, \\ \mathbf{E}[Z_t^4] &= \frac{3}{4t^2}. \end{aligned} \tag{3.16}$$

Remark 3.7 (Is $\mathcal{Z}$ Gaussian?)**.**
We conjecture that there is a unique limit process $\mathcal{Z}$ in Proposition 3.6. Moreover, we note that $\mathbf{V}[Z_t]$ and $\mathbf{E}[Z_t^4]$ are in the relation if $Z_t \sim N(0, 1/2t)$, which raises the question whether $\mathcal{Z}$ is a Gaussian process.

3.2 Path properties: the tree-valued Fleming–Viot process near the leaves

Although the Kingman measure tree, X_∞, only arises as the long-time limit of the tree-valued Fleming–Viot process, $\mathcal{X} = (X_t)_{t\geq 0}$, near the leaves the geometry of X_t (for $t > 0$) and of X_∞ is similar. The reason is that the structure near the leaves of X_∞ or X_t only depends on resampling events in the (very) recent past. Hence, we expect that the following results hold.

Conjecture 3.8.
The properties of X_∞ from Propositions 3.1 and 3.3 hold along the paths of $\mathcal{X}$. Furthermore we conjecture that the more ambitious refinements described in Remark 3.5 (see (3.9)*) also hold along the paths.*

We cannot prove this conjecture completely. However some (positive) answers are given in Theorems 1 (on the result corresponding to Proposition 3.1) and 3 (on the result corresponding to Proposition 3.3). In addition, Theorems 2 and 4 give two results on convergence to a Brownian motion along the tree-valued Fleming–Viot process.

The following theorem is proved in Section 4.4.

Theorem 1 (Uniform convergence of $\varepsilon N_\varepsilon$ along paths)**.**
Let $\mathcal{X} = (X_t)_{t\geq 0}$ with $X_t = \overline{(U_t, r_t, \mu_t)}$ be the tree-valued Fleming–Viot process (started in some $X_0 \in \mathbb{U}$). Moreover, let N_ε^t be the number of 2ε-balls needed to cover (U_t, r_t). Then,

$$\mathbf{P}\Big(\lim_{\varepsilon\to 0} \varepsilon N_\varepsilon^t = 2 \textit{ for all } t > 0\Big) = 1. \tag{3.17}$$

While the fluctuations in Proposition 3.2 are dealing with a fixed-time genealogy, we can view the fluctuations of the path $(\varepsilon N_\varepsilon^t)_{t\geq 0}$ arising in Theorem 1 in the limit $\varepsilon \to 0$. This program is now carried out along the tree-valued Fleming–Viot process.

In order to obtain a meaningful limit object, we consider time integrals. It is important to understand that the part of the time-t tree X_t which is at most ε apart from the treetop is independent of $\mathcal{F}_s \coloneqq \sigma(X_r : 0 \leq r \leq s)$ as long as $s \leq t - \varepsilon$. The following is proved in Section 4.5.

Theorem 2 (A Brownian motion in the tree-valued Fleming–Viot process)**.**
Let $\mathcal{X} = (X_t)_{t\geq 0}$ with $X_t = \overline{(U_t, r_t, \mu_t)}$ be the neutral tree-valued Fleming–Viot process (i.e. $\alpha = 0$) started in equilibrium, $X_0 \overset{d}{=} X_\infty$, and $\mathcal{B}_\varepsilon = (B_\varepsilon(t))_{t\geq 0}$ given by

$$B_\varepsilon(t) \coloneqq \sqrt{\frac{3}{2}} \int_0^t \Big(N_\varepsilon^s - \mathbf{E}[N_\varepsilon^\infty]\Big) ds. \tag{3.18}$$

Then,

$$\mathcal{B}_\varepsilon \xRightarrow{\varepsilon\to 0} \mathcal{B}, \tag{3.19}$$

where $\mathcal{B} = (B_t)_{t\geq 0}$ is a Brownian motion started in $B_0 = 0$.

Remark 3.9 (Expectation of N_ε^∞)**.**
In (3.18) one would rather like to replace $\mathbf{E}[N_\varepsilon^\infty]$ by $2/\varepsilon$ to measure the fluctuations around the limit profile. However this changes the limit which we are not able to identify. Precisely, we will see that $\widetilde{\mathcal{B}}_\varepsilon \coloneqq (\widetilde{B}_\varepsilon(t))_{t\geq 0}$, given by

$$\widetilde{B}_\varepsilon(t) \coloneqq \sqrt{\frac{3}{2}} \int_0^t \Big(N_\varepsilon^s - \frac{2}{\varepsilon}\Big) ds, \tag{3.20}$$

converges as $\varepsilon \to 0$ to a Brownian motion $\widetilde{\mathcal{B}}$ with *drift*, but unfortunately we cannot pin down the latter. Indeed from Proposition 3.2, in particular using boundedness of second moments, we see that, approximately, $\mathbf{E}[N_\varepsilon^\infty] \approx \frac{2}{\varepsilon}$ in the sense that $\varepsilon \cdot \mathbf{E}[N_\varepsilon^\infty] \xrightarrow{\varepsilon\to 0} 2$. However, this only implies $\mathbf{E}[N_\varepsilon^\infty] = 2/\varepsilon + o(1/\varepsilon)$ and the error term can be large. In order to sharpen this expansion to $\mathbf{E}[N_\varepsilon^\infty] = 2/\varepsilon + \mathcal{O}(1)$, we use results from [Tav84]. His Section 5.4 (with $\theta = 0$ and $i = \infty$) yields

$$\mathbf{E}[N_\varepsilon^\infty \cdots (N_\varepsilon^\infty - j + 1)] = \sum_{k=1}^\infty \rho_k(\varepsilon)(2k-1)\frac{(k-1)\cdots(k-j+1)\cdot k\cdots(k+j-2)}{(j-1)!}, \tag{3.21}$$

with $\rho_k(\varepsilon) = \exp(-k(k-1)\varepsilon/2)$. From this, writing $\delta \coloneqq \sqrt{\varepsilon}$ we also see that

$$\begin{aligned}
\mathbf{E}[N_\varepsilon^\infty] &= \frac{2}{\delta^2} \sum_{x\in\delta\mathbb{N}} \exp(-x(x-\delta)/2)(x-\delta/2)\delta \\
&= \frac{2}{\delta^2} \sum_{x\in\delta\mathbb{N}} \exp(-x^2/2)(1 + x\delta/2 + O(\delta^2))(x-\delta/2)\delta \\
&= \frac{2}{\delta^2} \int_0^\infty x e^{-x^2/2} dx + \frac{1}{\delta}\int_0^x (x^2-1)e^{-x^2/2} dx + \mathcal{O}(1) \\
&= \frac{2}{\varepsilon} + \mathcal{O}(1)
\end{aligned} \tag{3.22}$$

as $\varepsilon \to 0$. This, together with Theorem 2, implies that $\widetilde{\mathcal{B}}$ is of the form (3.20).

Now we come to a generalization of Proposition 3.3 to the tree-valued Fleming–Viot process. Together with Lemma 3.4, we obtain the following result on the Laplace transform of two randomly sampled points. The proof is based on martingale arguments which will also be useful in the proof of Theorem 6. Theorem 3 is proved in Section 6.4.

Theorem 3 (Small ball probabilities).
Let $\mathcal{X} = (X_t)_{t\geq 0}$ with $X_t = \overline{(U_t, r_t, \mu_t)}$ be the tree-valued Fleming–Viot process, started in some $X_0 \in \mathbb{U}$, and let Ψ^{12}_λ be as in Remark 2.5. Then

$$\lim_{\lambda\to\infty} \mathbf{P}\Big(\sup_{\varepsilon\leq t\leq T} |(\lambda+1)\Psi^{12}_\lambda(X_t) - 1| > \varepsilon\Big) = 0 \text{ for all } T < \infty, \varepsilon > 0. \tag{3.23}$$

Remark 3.10 (Convergence in probability versus almost sure convergence).
Denote by $F^t_1(2\varepsilon), \ldots, F^t_{N^t_\varepsilon}(2\varepsilon)$ the sizes of the N^t_ε balls of radius 2ε needed to cover (U_t, r_t). If we could show that $\mathbf{P}(\lim_{\lambda\to\infty}(\lambda+1)\Psi^{12}_\lambda(X_t) \xrightarrow{\lambda\to\infty} 1 \text{ for all } t > 0) = 1$, we could use Lemma 3.4 in order to see that

$$\mathbf{P}\Big(\frac{1}{\varepsilon}\sum_{i=1}^{N^t_\varepsilon}(F^t_i(2\varepsilon))^2 \xrightarrow{\varepsilon\to 0} 1 \text{ for all } t > 0\Big) = 1. \tag{3.24}$$

However, our proof of Theorem 3 is based on a computation involving the evolution of fourth moments of Ψ^{12}_λ in order to show tightness of $\{((\lambda+1)\Psi^{12}_\lambda(X_t))_{t\geq\varepsilon} : \lambda > 0\}$. Based on these computations, we can only claim convergence in probability rather than almost sure convergence.

Remark 3.11 (Possible refinement of Theorem 3).
As an ultimate goal one would want to prove that (compare with (3.8))

$$\sup_{0\leq t\leq T}\sup_{0\leq x<\infty}\Big|\frac{\varepsilon}{2}\sum_{i=1}^{N^t_\varepsilon}\mathbb{1}_{\{F^t_i(2\varepsilon)<\varepsilon x\}} - (1-e^{-2x})\Big| \xrightarrow{\varepsilon\to 0} 0 \text{ a.s.} \tag{3.25}$$

This would mean that the assertion that roughly the tree consists of $2/\varepsilon$ families of mean $\varepsilon/2$ exponentially distributed sizes holds at all times. Using our conclusions from Remark 3.5, this goal can be achieved if we show that (3.9) holds for $k = 1, 2, \ldots$ uniformly at all times. (While the case $k = 1$ is trivial, note that a combination of Theorem 3 and Lemma 3.4 gives (3.9) for $k = 2$.) In principle, the technique of our proof of Proposition 3.3 can be extended in order to obtain (3.9) for a given but arbitrary k which would require controlling higher order moments of Ψ^{12}_λ. If we could do this for general k then we would obtain a proof of (3.8). But since we are using Mathematica for these calculations the problem remains open.

Again, we can formulate a result on fluctuations. Integrating over time (to get a process rather than white noise) the quantity $(\lambda+1)\Psi^{12}(X_t) - 1$, which appears in Theorem 3, and using the right scaling, we again obtain a Brownian motion as the weak limit. The following result is proved in Section 6.5.

Theorem 4 (Another Brownian motion in the tree-valued Fleming–Viot process).
Let $\mathcal{X} = (X_t)_{t\geq 0}$ with $X_t = \overline{(U_t, r_t, \mu_t)}$ be the neutral tree-valued Fleming–Viot process (i.e. $\alpha = 0$) started in equilibrium, i.e., $X_0 \overset{d}{=} X_\infty$ and let $\mathcal{W}_\lambda = (W_\lambda(t))_{t\geq 0}$ be given by

$$W_\lambda(t) := \lambda\int_0^t ((\lambda+1)\Psi^{12}_\lambda(X_s) - 1)ds, \tag{3.26}$$

with Ψ^{12}_λ as in Example 2.5. Then,

$$\mathcal{W}_\lambda \xRightarrow{\lambda\to\infty} \mathcal{W}, \tag{3.27}$$

where $\mathcal{W} = (W_t)_{t\geq 0}$ *is a Brownian motion started in* $W_0 = 0$*.*

Remark 3.12 (A heuristic argument)**.**
Assume that λ is large. Then, $(\lambda+1)\Psi_\lambda^{12}(X_s) - 1$ depends approximately only on resampling events which happened within an interval $[s - C/\lambda, s]$ for some large C. In particular, on different time intervals (which are at least of order $1/\lambda$ apart), the increments of $\mathcal{W}_\lambda$ are approximately independent. Thus, it is reasonable to expect that the limiting process is a local martingale. In fact, using some stochastic calculus we can show that the limiting process is continuous (i.e. the family $\{\mathcal{W}_\lambda : \lambda > 0\}$ is tight in the space $\mathcal{C}_{\mathbb{R}}([0,\infty))$) and the limiting object of $(W_\lambda^2(t) - t)_{t\geq 0}$ is a local martingale as well. By Lévy's characterization of Brownian motion, $\mathcal{W}$ must be a Brownian motion.

3.3 Path properties: non-atomicity and mark functions

The calculus developed for the statements in Section 3.2 allows to obtain two further properties of the states of the tree-valued Fleming–Viot process $\mathcal{X} = (X_t)_{t\geq 0}$, $X_t = \overline{(U_t, r_t, \mu_t)}$, namely that the states are *atom-free* and admit a *mark function*. More precisely, Theorem 5 says that at no time it is possible to sample two individuals with distribution μ_t with distance zero; cf. Remark 3.13 below. Furthermore Theorem 6 says that we can assign marks to all individuals in the sense that μ_t has the form $\mu_t(du, da) = (\pi_{U_t})_* \mu_t(du)\delta_{\kappa_t(u)}(da)$ for some measurable function κ_t from U_t to A. These two theorems are proved in Section 7.

Theorem 5 (X_t never has an atom)**.**
Let $\mathcal{X} = (X_t)_{t\geq 0}$ *with* $X_t = \overline{(U_t, r_t, \mu_t)}$ *be the tree-valued Fleming–Viot process. Then,*

$$\mathbf{P}(\mu_t \textit{ has no atoms for all } t > 0) = 1. \tag{3.28}$$

Remark 3.13 (Interpretation and idea of the proof)**.**

1. At first glance the fact that μ_t is non-atomic for all $t > 0$ might seem to contradict the fact that the measure-valued Fleming–Viot diffusion is purely atomic for every $t > 0$. However, both properties are of different kind. The above theorem implies that randomly sampled individuals from the tree-valued Fleming–Viot process have distance of order 1, whereas genealogically the atomicity of the measure-valued Fleming–Viot diffusion expresses the fact that at every time $t > 0$ one can cover the state with a finite number of balls with radius $2t$.

2. The proof is based on the simple observation: for a measure $\mu \in \mathcal{M}_1(E)$,

$$\begin{aligned} \mu \text{ has no atom} \quad &\iff \quad \int \mu^{\otimes 2}(du, dv)\mathbb{1}_{\{r(u,v)=0\}} = 0 \\ &\iff \quad \lim_{\lambda\to\infty} \int \mu^{\otimes 2}(du, dv) e^{-\lambda r(u,v)} = 0. \end{aligned} \tag{3.29}$$

   Hence, the proof of (3.28) is based on a detailed analysis of the Laplace transform of the distance of two points, independently sampled with distribution μ_t.

The next goal is to establish that at any time there is a *mark function*. Briefly, the state $\overline{(U, r, \mu)}$ of a tree-valued population dynamics admits a mark function κ iff every individual $u \in U$ can be assigned a (unique) type $\kappa(u) \in A$. This situation occurs in particular in finite population models, e.g. in the Moran model. The question for the tree-valued Fleming–Viot model is whether types in the finite Moran model can change at a fast enough scale so that an individual can have several types in the large population limit. Such a situation can occur, if the cloud of very close relatives (as measured in the metric r) is not close in location (as measured in the type space A).

Definition 3.14 (Mark function)**.**
We say that $\overline{(U,r,\mu)} \in \mathbb{U}_A$ *admits a mark function if there is a measurable function* $\kappa : U \to A$ *such that for a random pair* $(\mathfrak{U}, \mathfrak{A})$ *with values in* $U \times A$ *and distribution* μ

$$\kappa(\mathfrak{U}) = \mathfrak{A} \quad \mu\text{-almost surely.} \tag{3.30}$$

Equivalently, $\overline{(U,r,\mu)} \in \mathbb{U}_A$ *admits a mark function if there is* $\nu \in \mathcal{M}_1(U)$ *with*

$$\mu(du, da) = \nu(du) \otimes \delta_{\kappa(u)}(da). \tag{3.31}$$

We set

$$\mathbb{U}_A^{\text{mark}} := \big\{\overline{(U,r,\mu)} \in \mathbb{U}_A : (U,r,\mu) \text{ admits a mark function}\big\}. \tag{3.32}$$

Remark 3.15 (mmm-spaces admitting a mark function are well-defined)**.**
Let us note that admitting a mark function is a property of an equivalence class. Assume $\overline{(U,r,\mu)} = \overline{(U',r',\mu')} \in \mathbb{U}_A$ (with an isometry $\varphi : U' \to U$ as in (2.2)), where $\overline{(U,r,\mu)}$ admits a mark function $\kappa : U \to A$, i.e. (3.31) holds. Then, clearly for $\kappa' := \kappa \circ \varphi$ we have

$$\mu'(du, da) = (\varphi, \mathrm{id})_* \mu(du, da) = (\varphi, \mathrm{id})_* \nu(du) \otimes \delta_{\kappa(u)}(da) = \varphi_* \nu(du) \otimes \delta_{\kappa(\varphi(u))}(da). \tag{3.33}$$

In other words, (U', r', μ') admits the mark function $\kappa' = \kappa \circ \varphi$.

Theorem 6 (X_t admits a mark function for all t)**.**
Let $\mathcal{X} = (X_t)_{t \geq 0}$*,* $X_t = \overline{(U_t, r_t, \mu_t)}$ *be the tree-valued Fleming–Viot-dynamics. Then,*

$$\mathbf{P}\big(X_t \in \mathbb{U}_A^{\text{mark}} \text{ for all } t > 0\big) = 1. \tag{3.34}$$

Remark 3.16 (Mark functions and the lookdown process)**.**
For a series of exchangeable population models it is possible to construct the state of an infinite population via the lookdown construction [DK96, DK99]. This construction immediately allows to define a mark function on a countable number of individuals specifying their types at all times, which suggests that (3.34) should hold. However, the metric space read off from the lookdown process is not complete, and the mark function is not continuous. Therefore, there is no way to extend the mark function given through the lookdown process to the completion of the corresponding metric space. Instead, our proof of Theorem 6 in Section 7.2 uses again martingale arguments and moment computations.

3.4 Strategy of proofs

The proofs of our results are of two types. On the one hand, the proofs of Propositions 3.1 and 3.2, Theorems 1 and 2 use as the basic tools the fine properties of coalescent times in Kingman's coalescent. This means they are carried out without specific martingale properties of the tree-valued Fleming–Viot process. On the other hand, Propositions 3.3 and 3.6, Theorems 3, 4, 5 and 6 are proved by calculating expectations (moments) of polynomials, which is possible by using the martingale problem for the tree-valued Fleming–Viot process. The polynomials we have to consider here (see also Remark 2.5) are either Ψ_λ^{12} or $\widehat{\Psi}_\lambda^{12}$, i.e. polynomials based on the test functions $\varphi(\underline{\underline{r}}, \underline{a}) = \exp(-\lambda r_{12})$ or $\varphi(\underline{\underline{r}}, \underline{a}) = \exp(-\lambda r_{12}) \mathbb{1}_{\{a_1 = a_2\}}$ and products, powers and linear combinations thereof. For the calculations of the moments of this type we develop some methodology which we explain in Section 5.

Propositions 3.1 and 3.2, Theorems 1 and 2 are proved in Section 4 while Propositions 3.3 and 3.6, Theorems 3 and 4 are proved in Section 6. The latter results are then used to prove Theorems 5 and 6 in Section 7.

4 Proof of Propositions 3.1 and 3.2 and of Theorems 1 and 2

4.1 Preparation: times in the Kingman coalescent

Recall that $T_n = S_{n+1}/\binom{n+1}{2} + S_{n+2}/\binom{n+2}{2} + \cdots$ is the time the Kingman coalescent needs to go down to n lines, where $S_2, S_3, \dots$ are i.i.d. exponential random variables with rate 1. Before we begin, we prove some simple results on the times T_n.

Lemma 4.1 (Moments and exponential moments of T_n)**.**
Let T_n be the time the Kingman coalescent needs to go from infinitely many to n lines. Then,

$$\begin{aligned}\mathbf{E}[T_n] &= \frac{2}{n},\\ \mathbf{E}\big[(T_n-2/n)^2\big] &= \frac{4}{3n^3}(1+\mathcal{O}(1/n)),\\ \mathbf{E}\big[(T_n-2/n)^3\big] &= \frac{16}{5n^5}(1+\mathcal{O}(1/n)),\\ \mathbf{E}\big[(T_n-2/n)^4\big] &= \frac{16}{9n^6}(1+\mathcal{O}(1/n)),\\ \mathbf{E}\big[(T_n-2/n)^6\big] &= \frac{64}{27n^9}(1+\mathcal{O}(1/n)),\\ \mathbf{E}\big[(T_n-2/n)^8\big] &= \frac{4^4}{3^4n^{12}}(1+\mathcal{O}(1/n)),\\ \mathbf{E}[e^{-\lambda T_n}] &\lesssim e^{-\frac{4}{3}(\frac{\lambda}{n}\wedge\frac{\sqrt{\lambda}}{2})}, \quad \lambda \geq 0.\end{aligned} \tag{4.1}$$

Proof. Recall that $\mathbf{E}[(S_i-1)^k] = k!\sum_{i=0}^k (-1)^i/i!$. We start by writing

$$\mathbf{E}[T_n] = \sum_{i=n+1}^\infty \frac{\mathbf{E}[S_i]}{\binom{i}{2}} = \sum_{i=n+1}^\infty \frac{2}{i(i-1)} = 2\sum_{i=n+1}^\infty \frac{1}{i-1} - \frac{1}{i} = \frac{2}{n}. \tag{4.2}$$

Next,

$$\begin{aligned}\mathbf{E}[(T_n-2/n)^2] = \mathbf{Var}[T_n] &= \sum_{i=n+1}^\infty \frac{4\mathbf{Var}[S_i]}{i^2(i-1)^2} = 4\sum_{i=n+1}^\infty \frac{1}{i^2(i-1)^2}\\ &= 4\int_n^\infty \frac{1}{x^4}dx + \mathcal{O}(1/n^4) = \frac{4}{3n^3}(1+\mathcal{O}(1/n)).\end{aligned} \tag{4.3}$$

For third moments, using $\mathbf{E}[(S_i-1)^3] = 2$

$$\begin{aligned}\mathbf{E}[(T_n-2/n)^3] &= \mathbf{E}\Big[\Big(\sum_{i=n+1}^\infty \frac{2}{i(i-1)}(S_i-1)\Big)^3\Big]\\ &= \sum_{i=n+1}^\infty \frac{2^3}{i^3(i-1)^3}\mathbf{E}[(S_i-1)^3]\\ &= \frac{16}{5n^5}(1+\mathcal{O}(1/n)),\end{aligned} \tag{4.4}$$

For fourth moments,

$$\begin{aligned}\mathbf{E}[(T_n-2/n)^4] &= \mathbf{E}\Big[\Big(\sum_{i=n+1}^{\infty}\frac{2}{i(i-1)}(S_i-1)\Big)^4\Big]\\ &= \sum_{i=n+1}^{\infty}\frac{2^4}{i^4(i-1)^4}\mathbf{E}[(S_i-1)^4]\\ &\quad+\sum_{\substack{i,j=n+1\\ i\neq j}}^{\infty}\frac{4}{i^2(i-1)^2}\frac{4}{j^2(j-1)^2}\mathbf{E}[(S_i-1)^2]\cdot\mathbf{E}[(S_j-1)^2] \\ &= \Big(\sum_{i=n+1}^{\infty}\frac{4}{i^2(i-1)^2}\mathbf{E}[(S_i-1)^2]\Big)^2+\mathcal{O}(1/n^7)\\ &= \frac{16}{9n^6}(1+\mathcal{O}(1/n))\end{aligned}\tag{4.5}$$

For sixth moments,

$$\begin{aligned}\mathbf{E}[(T_n-2/n)^6] &= \mathbf{E}\Big[\Big(\sum_{i=n+1}^{\infty}\frac{2}{i(i-1)}(S_i-1)\Big)^6\Big]\\ &= \Big(\sum_{i=n+1}^{\infty}\frac{4}{i^2(i-1)^2}\mathbf{E}[(S_i-1)^2]\Big)^3+\mathcal{O}(1/n^{10})\\ &= \frac{64}{27n^9}(1+\mathcal{O}(1/n)).\end{aligned}\tag{4.6}$$

With analogous calculations, the results for the 8th moment follows.

Finally for the exponential moments, we compute for any $\lambda\geq 0$

$$\begin{aligned}\mathbf{E}[e^{-\lambda T_n}] &= \prod_{i=n+1}^{\infty}\frac{\binom{i}{2}}{\binom{i}{2}+\lambda} = \exp\Big(\sum_{i=n+1}^{\infty}\log\Big(1-\frac{\lambda}{\binom{i}{2}+\lambda}\Big)\Big)\\ &\leq \exp\Big(-\sum_{i=n+1}^{\infty}\frac{\lambda}{\binom{i}{2}+\lambda}\Big)\leq \exp\Big(-\sum_{i=(n+1)\vee\lceil\sqrt{4\lambda}+1\rceil}^{\infty}\frac{\lambda}{\binom{i}{2}+\lambda}\Big)\\ &\leq \exp\Big(-\sum_{i=(n+1)\vee\lceil\sqrt{4\lambda}+1\rceil}^{\infty}\frac{\frac{2}{3}\lambda}{\binom{i}{2}}\Big) = \exp\Big(-\frac{4}{3}\cdot\frac{\lambda}{n\vee\lceil\sqrt{4\lambda}\rceil}\Big)\lesssim e^{-\frac{4}{3}(\frac{\lambda}{n}\wedge\frac{\sqrt{\lambda}}{2})}.\end{aligned}\tag{4.7}$$

□

4.2 Proof of Proposition 3.1

Let T_n be as in the last subsection. Then, (3.1) is equivalent to

$$nT_n\xrightarrow{n\to\infty}2.\tag{4.8}$$

In order to see this, note that $N_{T_n}=n$ by definition and

$$\{T_n\geq\varepsilon\}=\{N_\varepsilon\geq n\}.\tag{4.9}$$

Since $T_n\downarrow 0$ as $n\to\infty$ (and $N_\varepsilon\uparrow\infty$ as $\varepsilon\to 0$), the equivalence of (3.1) and (4.8) follows.

For (4.8), it suffices to note that

$$\mathbf{P}(|nT_n-2|>\varepsilon)\leq\frac{\mathbf{E}[(T_n-2/n)^4]}{(\varepsilon/n)^4}\leq\frac{16}{9\varepsilon^4n^2}(1+\mathcal{O}(1/n)).\tag{4.10}$$

by Lemma 4.1. Since the right hand side is summable, $\limsup_{n\to\infty}|nT_n-2|\leq\varepsilon$ almost surely for all $\varepsilon>0$. In other words, $nT_n\to 2$ almost surely.

4.3 Proof of Proposition 3.2

By the Lindeberg–Feller central limit theorem, we see from the moment computations of Lemma 4.1 that

$$\frac{T_n - 2/n}{\sqrt{4/(3n^3)}} \xRightarrow{n\to\infty} Z. \tag{4.11}$$

Recalling (4.9), we set

$$a_\varepsilon(x) := \Big\lfloor \frac{2}{\varepsilon} + x\sqrt{2/(3\varepsilon)} \Big\rfloor = \frac{2}{\varepsilon} + x\sqrt{2/(3\varepsilon)} + \mathcal{O}(1), \tag{4.12}$$

such that for every $x \in \mathbb{R}$:

$$\begin{aligned} \mathbf{P}\Big(\frac{N_\varepsilon - 2/\varepsilon}{\sqrt{2/(3\varepsilon)}} > x\Big) &= \mathbf{P}(T_{a_\varepsilon(x)} > \varepsilon) \\ &= \mathbf{P}\Big(\frac{T_{a_\varepsilon(x)} - 2/a_\varepsilon(x)}{\sqrt{4/(3a_\varepsilon(x)^3)}} > \underbrace{\frac{\varepsilon - 2/a_\varepsilon(x)}{\sqrt{4/(3a_\varepsilon(x)^3)}}}_{=x(1+\mathcal{O}(\sqrt{\varepsilon}))}\Big) \\ &\xrightarrow{\varepsilon\to\infty} \mathbf{P}(Z > x), \end{aligned} \tag{4.13}$$

which implies (3.2).

However, we also need to show convergence of moments up to fourth order. We write

$$\mathbf{E}\Big[\Big(\frac{N_\varepsilon - 2/\varepsilon}{\sqrt{2/(3\varepsilon)}}\Big)^2\Big] = 2\int_0^\infty x\mathbf{P}\Big(\Big|\frac{N_\varepsilon - 2/\varepsilon}{\sqrt{2/(3\varepsilon)}}\Big| > x\Big)dx, \tag{4.14}$$

$$\mathbf{E}\Big[\Big(\frac{N_\varepsilon - 2/\varepsilon}{\sqrt{2/(3\varepsilon)}}\Big)^4\Big] = 4\int_0^\infty x^3\mathbf{P}\Big(\Big|\frac{N_\varepsilon - 2/\varepsilon}{\sqrt{2/(3\varepsilon)}}\Big| > x\Big)dx. \tag{4.15}$$

To estimate the right hand side of (4.15) we first show that for a suitably chosen $\delta > 0$ and $\sqrt{6-\delta} \le c < \sqrt{6}$ we have

$$\int_{c/\sqrt{\varepsilon}}^\infty x^3\mathbb{P}\Big(\frac{N_\varepsilon - 2/\varepsilon}{\sqrt{2/(3\varepsilon)}} < -x\Big) = \int_{c/\sqrt{\varepsilon}}^{\sqrt{6/\varepsilon}} x^3\mathbb{P}\Big(\frac{N_\varepsilon - 2/\varepsilon}{\sqrt{2/(3\varepsilon)}} < -x\Big) \xrightarrow{\varepsilon\to 0} 0, \tag{4.16}$$

where the equality follows because for $x \ge \sqrt{6/\varepsilon}$ the integrand is identically 0. Using the exponential Chebyshev inequality, we obtain for all $\lambda_{y,\varepsilon} \ge 0$

$$\begin{aligned} \int_{c/\sqrt{\varepsilon}}^{\sqrt{6/\varepsilon}} x^3\mathbb{P}\Big(\frac{N_\varepsilon - 2/\varepsilon}{\sqrt{2/(3\varepsilon)}} < -x\Big)\,dx &= \int_{c/\sqrt{\varepsilon}}^{\sqrt{6/\varepsilon}} x^3\mathbb{P}\Big(N_\varepsilon < \frac{2}{\varepsilon} - x\sqrt{2/(3\varepsilon)}\Big)\,dx \\ &= \frac{9}{4}\int_{c\sqrt{2/3}}^{2} \frac{y^3}{\varepsilon^2}\mathbb{P}\Big(N_\varepsilon \le \lfloor\frac{2-y}{\varepsilon}\rfloor\Big)\,dy = \frac{9}{4}\int_{c\sqrt{2/3}}^{2} \frac{y^3}{\varepsilon^2}\mathbb{P}\Big(T_{\lfloor\frac{2-y}{\varepsilon}\rfloor} \le \varepsilon\Big)\,dy \\ &\le \frac{9}{4}\int_{c\sqrt{2/3}}^{2} \frac{y^3}{\varepsilon^2}e^{\lambda_{y,\varepsilon}\varepsilon}\mathbb{E}\Big[e^{-\lambda_{y,\varepsilon}T_{\lfloor\frac{2-y}{\varepsilon}\rfloor}}\Big]\,dy, \end{aligned}$$

now taking the lower bound for c, setting $\delta' = 2\delta/3$ and using (4.7) we get

$$\begin{aligned} &\le \frac{9}{4}\int_{\sqrt{4-\delta'}}^{2} \frac{y^3}{\varepsilon^2}e^{\lambda_{y,\varepsilon}\varepsilon}\mathbb{E}\Big[e^{-\lambda_{y,\varepsilon}T_{\lfloor\frac{2-y}{\varepsilon}\rfloor}}\Big]\,dy \\ &\lesssim \frac{9}{4}\int_{\sqrt{4-\delta'}}^{2} \frac{y^3}{\varepsilon^2}\exp\Big\{\lambda_{y,\varepsilon}\varepsilon - \frac{4}{3}\Big(\frac{\lambda_{y,\varepsilon}\varepsilon}{2-y} \wedge \frac{\sqrt{\lambda_{y,\varepsilon}}}{2}\Big)\Big\}\,dy. \end{aligned} \tag{4.17}$$

Now choose $\lambda_{y,\varepsilon} = \frac{(2-y+1/2)^2}{\varepsilon^2}$ and let $\delta' = 0.39$ be the solution of $\sqrt{4-\delta'} = 1.9$. For $y \in (1.9, 2]$ we have

$$\frac{\lambda_{y,\varepsilon}\varepsilon}{2-y} \wedge \frac{\sqrt{\lambda_{y,\varepsilon}}}{2} = \frac{(2-y+1/2)^2}{\varepsilon(2-y)} \wedge \frac{2-y+1/2}{2\varepsilon} = \frac{2-y+1/2}{2\varepsilon}. \tag{4.18}$$

Thus,

$$\lambda_{y,\varepsilon}\varepsilon - \frac{4}{3}\Big(\frac{\lambda_{y,\varepsilon}\varepsilon}{2-y} \wedge \frac{\sqrt{\lambda_{y,\varepsilon}}}{2}\Big) = -\frac{1}{\varepsilon}\Big(-\frac{55}{12} + \frac{13}{3}y - y^2\Big). \tag{4.19}$$

It is easy to see that on the interval $[1.9, 2]$ the function $y \mapsto (-\frac{55}{12} + \frac{13}{3}y - y^2)$ is bounded below by $a = 0.04$ (its value in 1.9). It follows

$$\int_{c/\sqrt{\varepsilon}}^{\infty} x^3 \mathbb{P}\Big(\frac{N_\varepsilon - 2/\varepsilon}{\sqrt{2/(3\varepsilon)}} < -x\Big)\, dx \le c' \frac{1}{\varepsilon^2} e^{-a/\varepsilon} \xrightarrow{\varepsilon \to 0} 0 \tag{4.20}$$

for a suitable constant $c' > 0$, and hence we have shown (4.16).

In order to show convergence of fourth (and second) moments, using (4.15), since $\mathbf{P}\Big(\Big|\frac{N_\varepsilon - 2/\varepsilon}{\sqrt{2/(3\varepsilon)}}\Big| > x\Big) \xrightarrow{\varepsilon \to 0} \mathbf{P}(|Z| > x)$ pointwise, we need to show that there is an integrable function dominating

$$x^3 \left(\mathbf{P}\left(\frac{N_\varepsilon - 2/\varepsilon}{\sqrt{2/(3\varepsilon)}} > x\right) + \mathbf{P}\left(\frac{N_\varepsilon - 2/\varepsilon}{\sqrt{2/(3\varepsilon)}} < -x\right) \mathbb{1}_{\{x \le c/\sqrt{\varepsilon}\}}\right), \tag{4.21}$$

for some $c > 0$ and $x \ge 0$. For this, we get, by the Markov inequality and (4.6)

$$\begin{aligned} &\mathbf{P}\Big(\Big|\frac{N_\varepsilon - 2/\varepsilon}{\sqrt{2/(3\varepsilon)}}\Big| > x\Big) \\ &\quad = \mathbf{P}\Big(T_{a_\varepsilon(x)} - 2/a_\varepsilon(x) > \varepsilon - 2/a_\varepsilon(x)\Big) + \mathbf{P}\Big(T_{a_\varepsilon(-x)} - 2/a_\varepsilon(-x) \le \varepsilon - 2/a_\varepsilon(-x)\Big) \\ &\quad \le \frac{\mathbf{E}[(T_{a_\varepsilon(x)} - 2/a_\varepsilon(x))^6]}{(\varepsilon - 2/a_\varepsilon(x))^6} + \frac{\mathbf{E}[(T_{a_\varepsilon(-x)} - 2/a_\varepsilon(-x))^6]}{(\varepsilon - 2/a_\varepsilon(-x))^6} \\ &\quad = \frac{64(1 + \mathcal{O}(1/a_\varepsilon(x))}{27 a_\varepsilon(x)^9 (x\sqrt{\varepsilon^3/6}(1 + \mathcal{O}(\sqrt{\varepsilon})))^6} + \frac{64(1 + \mathcal{O}(1/a_\varepsilon(x))}{27 a_\varepsilon(-x)^6 (-x\sqrt{\varepsilon^3/6}(1 + \mathcal{O}(\sqrt{\varepsilon})))^6} \\ &\quad = \frac{2(1 + \mathcal{O}(1/a_\varepsilon(x))}{x^6(1 + \mathcal{O}(\sqrt{\varepsilon}))} \le \frac{2}{x^6(1 + \mathcal{O}(\varepsilon))} + \mathcal{O}\Big(\frac{\varepsilon}{x^6(1 + x\sqrt{\varepsilon/6})}\Big), \end{aligned} \tag{4.22}$$

since

$$\frac{1}{a_\varepsilon(x)} = \frac{1}{\frac{2}{\varepsilon} + x\sqrt{2/(3\varepsilon)} + \mathcal{O}(1)} = \frac{\varepsilon}{2} \frac{1}{1 + x\sqrt{\varepsilon/6} + \mathcal{O}(\varepsilon)}. \tag{4.23}$$

Since the area $x < 0$ is restricted to $x \le c/\sqrt{\varepsilon}$ in (4.21), the $\mathcal{O}(\cdot)$-term on the right hand side of (4.22) does not have a pole. It is now easy to obtain an integrable function dominating (4.21), leading to (3.3).

4.4 Proof of Theorem 1

By Proposition 2.11 5. (see [DGP12, Thm. 2] for details) the tree-valued Fleming–Viot process with selection has a law which is absolutely continuous with respect to the neutral process. Therefore it suffices to consider the neutral case, $\alpha = 0$. We observe that for $\alpha = 0$ the claim is not affected by mutation. Moreover, it suffices to deal with the case $X_0 \overset{d}{=} X_\infty$. The reason is that (3.17) is equivalent to the assertion that $\lim_{\varepsilon\to 0} \varepsilon N_\varepsilon^t = 2$ for all $t > \delta$ holds for all $\delta > 0$, and N_ε^t is independent of X_0 for $\varepsilon < t$.

Let

$$T_n^t \coloneqq \inf\{\varepsilon > 0 : (U_t, r_t) \text{ can be covered by } n \text{ balls of radius } 2\varepsilon\}, \tag{4.24}$$

i.e. T_n^t is the minimal time we have to go back from time t such that we have n ancestral lineages. It suffices to show (see around (4.8)) that $\mathbf{P}(nT_n^t \xrightarrow{n\to\infty} 2 \text{ for all } t > 0) = 1$. To prove this, we need to extend the proof of Proposition 3.1. It suffices to show that $nT_n^t \to 2$ uniformly for $0 \le t \le 1$ (if $X_0 \overset{d}{=} X_\infty$).

First, by Lemma 4.1, for all $t \ge 0$ we have

$$\mathbf{E}\big[\big(T_n^t - \mathbf{E}[T_n^t]\big)^8\big] \lesssim \frac{1}{n^{12}}. \tag{4.25}$$

Therefore considering the process along a discrete grid, we have for any $\varepsilon > 0$,

$$\begin{aligned}\mathbf{P}\Big(\sup_{k=0,\dots,n^2} |nT_n^{k/n^2} - 2| > \varepsilon\Big) &\le \sum_{k=0}^{n^2} \mathbf{P}\big(|nT_n^{k/n^2} - 2| > \varepsilon\big) \\ &\lesssim n^2 \frac{\mathbf{E}\big[\big(T_n^0 - \mathbf{E}[T_n^0]\big)^8\big]}{(\varepsilon/n)^8} \lesssim \frac{1}{\varepsilon^8 n^2}.\end{aligned} \tag{4.26}$$

Since the right hand side is summable, $\sup_{k=1,\dots,n^2} |nT_n^{k/n^2} - 2| \xrightarrow{n\to\infty} 0$ almost surely by the Borel–Cantelli lemma. Now we need this in continuous time and derive for the difference $(nT_n^{t/n^2} - 2)$ bounds from above and from below.

First observe that $\{T_n^t > \varepsilon\} \subseteq \{T_n^s > \varepsilon - (t-s)\}$ for $t - \varepsilon \le s \le t$ for tree-valued Fleming–Viot process. (This property holds in every population model, arising as a diffusion limit from an individual based population where we can define ancestors, since the ancestors at time $t - \varepsilon$ of the population at time t must then be ancestors at time $t - \varepsilon = s - \varepsilon + (t-s)$ of the population at time $t - \varepsilon < s < t$.) We can now write, for $\varepsilon > 0$ and $n > 2/\varepsilon$:

$$\begin{aligned}\mathbf{P}\left(\sup_{0\le t\le 1} nT_n^t > 2+\varepsilon\right) &\le \mathbf{P}\Big(\sup_{0\le t\le 1} T_n^{\lfloor tn^2\rfloor/n^2} > \frac{2+\varepsilon}{n} - \Big(t - \frac{\lfloor tn^2\rfloor}{n^2}\Big)\Big) \\ &\le \mathbf{P}\Big(\sup_{k=0,\dots,n^2} T_n^{k/n^2} > \frac{2+\varepsilon}{n} - \frac{1}{n^2}\Big) \\ &\le \mathbf{P}\Big(\sup_{k=0,\dots,n^2} T_n^{k/n^2} > \frac{2+\varepsilon/2}{n}\Big) \lesssim \frac{1}{\varepsilon^8 n^2}.\end{aligned} \tag{4.27}$$

Hence $\limsup_{n\to\infty} \sup_{0\le t\le 1} nT_n^t \le 2$ almost surely, by the Borel–Cantelli lemma.

For the other direction of the inequality we use $\{T_n^t < \varepsilon\} \subseteq \{T_n^s < \varepsilon + s - t\}$ for $s \ge t$, to get

$$\begin{aligned}\mathbf{P}\left(\sup_{0\le t\le 1} nT_n^t < 2-\varepsilon\right) &\le \mathbf{P}\Big(\sup_{0\le t\le 1} T_n^{\lceil tn^2\rceil/n^2} < \frac{2-\varepsilon}{n} + \frac{\lceil tn^2\rceil}{n^2} - t\Big) \\ &\le \mathbf{P}\Big(\sup_{k=0,\dots,n^2} T_n^{k/n^2} < \frac{2-\varepsilon}{n} + \frac{1}{n^2}\Big) \\ &\le \mathbf{P}\Big(\sup_{k=0,\dots,n^2} T_n^{k/n^2} < \frac{2-\varepsilon/2}{n}\Big) \lesssim \frac{1}{\varepsilon^8 n^2}.\end{aligned} \tag{4.28}$$

Hence $\liminf_{n\to\infty} \sup_{0\le t\le 1} nT_n^t \ge 2$ almost surely.

Combining both, the estimate from above and from below we obtain the assertion of Theorem 1.

4.5 Proof of Theorem 2

We proceed in the following four steps.

- **Step 0**: Warm up; computation of the first two moments of $B_\varepsilon(t) - B_\varepsilon(s)$.
- **Step 1**: Computation of the first two conditional moments of $B_\varepsilon(t) - B_\varepsilon(s)$.
- **Step 2**: The family $(B_\varepsilon)_{\varepsilon>0}$ is tight in $\mathcal{C}_\mathbb{R}([0,\infty))$.
- **Step 3**: For $(B(t))_{t\geq 0}$ a limit point $(B(t))_{t\geq 0}$ as well as $(B(t)^2 - t)_{t\geq 0}$ are martingales.

Throughout we let $(\mathcal{F}_t)_{t\geq 0}$ be the canonical filtration of $\mathcal{X} = (X_t)_{t\geq 0}$.

Step 0: Computation of first two moments of $B_\varepsilon(t) - B_\varepsilon(s)$. The first moment of $B_\varepsilon(t) - B_\varepsilon(s)$ equals 0 since by assumption the tree-valued Fleming–Viot process is in equilibrium.

For the second moment, we start by noting that (see Proposition 3.2)

$$N_\varepsilon^s = \frac{2}{\varepsilon} + \sqrt{\frac{2}{3\varepsilon}} Z^s + o\Big(\frac{1}{\sqrt{\varepsilon}}\Big) \tag{4.29}$$

for some random variable $Z^s \sim N(0,1)$. Note that N_ε^s and N_δ^t are independent given $(t-\delta,t] \cap (s-\varepsilon,s] = \emptyset$. (The reason is that in this case N_ε^s depends on resampling events in the time interval $(s-\varepsilon,s]$ while N_δ^t only depends on resampling events in $(t-\delta,t]$, and these two sets of events are independent.) Without loss of generality, we set $s=0$ and compute the variance of $B_\varepsilon(t)$ as

$$\begin{aligned}\mathbf{Var}[B_\varepsilon(t)] &= 3\int_0^t \int_0^s \mathbf{Cov}(N_\varepsilon^r, N_\varepsilon^s) dr ds = 3\int_0^t \int_{0\vee(s-\varepsilon)}^s \mathbf{Cov}(N_\varepsilon^r, N_\varepsilon^s) dr ds \\ &= 3\int_0^t \int_0^{\varepsilon\wedge t} \mathbf{Cov}(N_\varepsilon^{s-\delta}, N_\varepsilon^s) d\delta ds \overset{\varepsilon\to 0}{\approx} 6t \cdot \int_0^\varepsilon \mathbf{Cov}(N_\varepsilon^0, N_\varepsilon^\delta) d\delta.\end{aligned} \tag{4.30}$$

In order to compute the integrand of the last expression, we decompose $N_\varepsilon^0 = N_{\varepsilon-\delta}^0 - (N_{\varepsilon-\delta}^0 - N_\varepsilon^0)$. Now $N_{\varepsilon-\delta}^0 - N_\varepsilon^0$ is independent of N_ε^δ. The former is the number of lines the tree at time 0 looses between times $\varepsilon-\delta$ and ε in the past, and therefore only depends on resampling events between times $-\varepsilon$ and $\delta-\varepsilon$. The latter only depends on resampling events between times $\delta-\varepsilon$ and δ. Hence,

$$\mathbf{Cov}(N_\varepsilon^0, N_\varepsilon^\delta) = \mathbf{Cov}(N_{\varepsilon-\delta}^0, N_\varepsilon^\delta). \tag{4.31}$$

Consider now the dual representation of our equilibrium by the Kingman coalescent. Let K_i^N be number of lines of a subtree, starting with N lines, in a tree starting with ∞ many lines, at the time the big tree has i lines. In [PWW11, Lemma 4.1] it is shown that

$$\mathbf{E}[K_i^N] = \frac{iN}{N+i-1}. \tag{4.32}$$

Hence, for independent $Z, Z' \sim N(0,1)$,

$$\begin{aligned}
\mathbf{Cov}(N_\varepsilon^0, N_\varepsilon^\delta) &= \mathbf{Cov}(N_{\varepsilon-\delta}^0, N_\varepsilon^\delta) \\
&= \mathbf{Cov}(N_{\varepsilon-\delta}^0, \mathbf{E}[N_\varepsilon^\delta | N_\delta^\delta, N_{\varepsilon-\delta}^0]) \\
&= \mathbf{Cov}(N_{\varepsilon-\delta}^0, \mathbf{E}[K_{N_{\varepsilon-\delta}^0}^{N_\delta^\delta} | N_\delta^\delta, N_{\varepsilon-\delta}^0]) \\
&= \mathbf{Cov}\Big(N_{\varepsilon-\delta}^0, \frac{N_{\varepsilon-\delta}^0 \cdot N_\delta^\delta}{N_{\varepsilon-\delta}^0 + N_\delta^\delta - 1}\Big) \\
&\overset{\varepsilon\to 0}{\approx} \mathbf{Cov}\Bigg(\sqrt{2/(3(\varepsilon-\delta))}Z + o(1/\sqrt{\varepsilon}), \\
&\qquad \frac{\Big(\frac{2}{\varepsilon-\delta} + \sqrt{2/(3(\varepsilon-\delta))}Z + o(\sqrt{1/\varepsilon}\,)\Big)\Big(\frac{2}{\delta} + \sqrt{2/(3\delta)}Z' + o(\sqrt{1/\varepsilon}\,)\Big)}{\frac{2}{\varepsilon-\delta} + \frac{2}{\delta} + \sqrt{2/(3(\varepsilon-\delta))}Z + \sqrt{2/(3\delta)}Z' + o(1/\sqrt{\varepsilon}\,)}\Bigg) \\
&= \frac{2}{\varepsilon}\mathbf{Cov}\Bigg(\sqrt{2/(3(\varepsilon-\delta))}Z + o(1/\sqrt{\varepsilon}\,), \\
&\qquad \frac{\Big(1 + \sqrt{(\varepsilon-\delta)/6}Z + o(\sqrt{\varepsilon}\,)\Big)\Big(1 + \sqrt{\delta/6}Z' + o(\sqrt{\varepsilon}\,))\Big)}{1 + \frac{\delta}{\varepsilon}\sqrt{(\varepsilon-\delta)/6)}Z + \frac{\varepsilon-\delta}{\varepsilon}\sqrt{\delta/6}Z' + o(\sqrt{\varepsilon}\,)}\Bigg) \\
&= \frac{2}{\varepsilon}\mathbf{Cov}\Big(\sqrt{2/(3(\varepsilon-\delta))}Z + o(1/\sqrt{\varepsilon}\,), \\
&\qquad\qquad \Big(\Big(1 + \sqrt{(\varepsilon-\delta)/6}Z + \sqrt{\delta/6}Z' + o(\sqrt{\varepsilon}))\Big) \\
&\qquad\qquad\qquad \cdot \Big(1 - \frac{\delta}{\varepsilon}\sqrt{(\varepsilon-\delta)/6)}Z - \frac{\varepsilon-\delta}{\varepsilon}\sqrt{\delta/6}Z' + o(\sqrt{\varepsilon}\,)\Big) \\
&= \frac{2}{\varepsilon}\mathbf{Cov}\Big(\sqrt{2/(3(\varepsilon-\delta))}Z + o(1/\sqrt{\varepsilon}\,), \frac{\varepsilon-\delta}{\varepsilon}\sqrt{(\varepsilon-\delta)/6}Z + \frac{\delta}{\varepsilon}\sqrt{\delta/6}Z' + o(\sqrt{\varepsilon}\,)\Big) \\
&= \frac{2(\varepsilon-\delta)}{3\varepsilon^2}(1 + o(1))
\end{aligned} \tag{4.33}$$

leading to

$$\mathbf{Var}[B_\varepsilon(t)] = 3t\int_0^\varepsilon \mathbf{Cov}(N_\varepsilon^0, N_\varepsilon^\delta)d\delta \overset{\varepsilon\to 0}{\approx} 3t\int_0^\varepsilon \frac{2\delta}{3\varepsilon^2}d\delta = t. \tag{4.34}$$

Step 1: Computation of first two conditional moments of $B_\varepsilon(t) - B_\varepsilon(s)$. We can compute the *first conditional moment* as

$$\mathbf{E}[B_\varepsilon(t) - B_\varepsilon(s) | \mathcal{F}_s] = \sqrt{\frac{3}{2}}\int_s^t \mathbf{E}[N_\varepsilon^r - \mathbf{E}[N_\varepsilon^\infty] | \mathcal{F}_s]dr = \sqrt{\frac{3}{2}}\int_s^{s+\varepsilon} \mathbf{E}[N_\varepsilon^r - \mathbf{E}[N_\varepsilon^\infty] | \mathcal{F}_s]\,dr \tag{4.35}$$

since we started in equilibrium and N_ε^r is independent of $\mathcal{F}_s$ for $r > s + \varepsilon$. So, by Proposition 3.2,

$$\mathbf{E}\big[\big(\mathbf{E}[B_\varepsilon(t) - B_\varepsilon(s) | \mathcal{F}_s]\big)^2\big] \lesssim \varepsilon^2\mathbf{E}[(N_\varepsilon^\infty - \mathbf{E}[N_\varepsilon^\infty])^2] \xrightarrow{\varepsilon\to 0} 0, \tag{4.36}$$

which implies

$$\mathbf{E}[B_\varepsilon(t) - B_\varepsilon(s) | \mathcal{F}_s] \xrightarrow{\varepsilon\to 0} 0 \qquad \text{in } L^2. \tag{4.37}$$

For the *second conditional moment*, we extend our calculation from Step 0. Here,

$$\begin{aligned}
\mathbf{E}[(B_\varepsilon(t) - B_\varepsilon(s))^2 | \mathcal{F}_s] &= 3\int_s^t \int_s^{r_1} \mathbf{E}[(N_\varepsilon^{r_1} - \mathbf{E}[N_\varepsilon^\infty])(N_\varepsilon^{r_2} - \mathbf{E}[N_\varepsilon^\infty]) | \mathcal{F}_s]dr_1 dr_2 \\
&= 3\int_{s+\varepsilon}^t \int_{s+\varepsilon}^{r_1} \mathbf{Cov}[N_\varepsilon^{r_1}, N_\varepsilon^{r_2}]dr_1 dr_2 + 3A_\varepsilon,
\end{aligned} \tag{4.38}$$

with

$$\begin{aligned}\mathbf{E}[|A_\varepsilon|] &= \mathbf{E}\Big[\Big|\int_s^t\int_s^{r_1\wedge(s+\varepsilon)}\mathbf{E}[(N_\varepsilon^{r_1}-\mathbf{E}[N_\varepsilon^\infty])(N_\varepsilon^{r_2}-\mathbf{E}[N_\varepsilon^\infty])|\mathcal{F}_s]dr_1dr_2\Big|\Big]\\ &= \mathbf{E}\Big[\Big|\int_s^{s+2\varepsilon}\int_s^{r_1\wedge(s+\varepsilon)}\mathbf{E}[|(N_\varepsilon^{r_1}-\mathbf{E}[N_\varepsilon^\infty])(N_\varepsilon^{r_2}-\mathbf{E}[N_\varepsilon^\infty])|\mathcal{F}_s]dr_1dr_2\Big|\Big]\\ &\le \int_s^{s+2\varepsilon}\int_s^{r_1\wedge(s+\varepsilon)}\mathbf{E}[|(N_\varepsilon^{r_1}-\mathbf{E}[N_\varepsilon^\infty])(N_\varepsilon^{r_2}-\mathbf{E}[N_\varepsilon^\infty])|]dr_1dr_2\\ &\le \int_s^{s+2\varepsilon}\int_s^{r_1}\mathbf{E}[|(N_\varepsilon^{r_1}-\mathbf{E}[N_\varepsilon^\infty])(N_\varepsilon^{r_2}-\mathbf{E}[N_\varepsilon^\infty])|]dr_1dr_2\\ &\le 2\varepsilon^2\mathbf{Var}[N_\varepsilon^\infty]\xrightarrow{\varepsilon\to 0}0\end{aligned}\tag{4.39}$$

by Proposition 3.2. So, combining the last two displays with (4.34),

$$\mathbf{E}[(B_\varepsilon(t)-B_\varepsilon(s))^2|\mathcal{F}_s]\xrightarrow{\varepsilon\to 0}t-s\qquad\text{in } L^1.\tag{4.40}$$

Step 2: The family of the laws of $(B_\varepsilon)_{\varepsilon>0}$ *on* $\mathcal{C}_\mathbb{R}([0,\infty))$ *is tight for* $\varepsilon\to 0$*.* We use the Kolmogorov–Chentsov criterion; see e.g. [Kal02, Corollary 14.9]. We bound the fourth moment of the increment in B_ε. We write $a_\varepsilon := \mathbf{E}[N_\varepsilon^\infty]$ such that, again making use of the independence of $N_\varepsilon^{s_2}$ and $N_\varepsilon^{s_1}$ if $|s_2-s_1|>\varepsilon$, as well as of Proposition 3.2, we estimate for fixed t and $\varepsilon\to 0$

$$\begin{aligned}\mathbf{E}[(B_\varepsilon(t))^4] &\lesssim \int_0^t\int_0^{s_1}\int_0^{s_2}\int_0^{s_3}\mathbf{E}\Big[\prod\nolimits_{i=1}^4(N_\varepsilon^{s_i}-a_\varepsilon)\Big]\,ds_4\,ds_3\,ds_2\,ds_1\\ &\lesssim \Big(\int_0^t\int_{0\vee(s_1-\varepsilon)}^{s_1}\mathbf{E}[(N_\varepsilon^{s_1}-a_\varepsilon)\cdot(N_\varepsilon^{s_2}-a_\varepsilon)]ds_2ds_1\Big)^2\\ &\quad+\int_0^t\int_{0\vee(s_1-\varepsilon)}^{s_1}\int_{0\vee(s_2-\varepsilon)}^{s_2}\int_{0\vee(s_3-\varepsilon)}^{s_3}\mathbf{E}\Big[\prod\nolimits_{i=1}^4(N_\varepsilon^{s_i}-a_\varepsilon)\Big]\,ds_4\,ds_3\,ds_2\,ds_1\\ &\lesssim \big(t(t\wedge\varepsilon)\mathbf{Var}[N_\varepsilon^\infty]\big)^2+t(t\wedge\varepsilon)^3\mathbf{E}[(N_\varepsilon^\infty-a_\varepsilon)^4]\\ &\lesssim t^2\end{aligned}\tag{4.41}$$

and the tightness follows.

Step 3: If $(B_t)_{t\ge 0}$ *is a limit point, then* $(B_t)_{t\ge 0}$ *as well as* $(B_t^2-t)_{t\ge 0}$ *are martingales.* Let $\mathcal{B}=(B_t)_{t\ge 0}$ be a weak limit point of $\{(B_\varepsilon(t))_{t\ge 0}:\varepsilon>0\}$, which has continuous paths by Step 2. We know from Step 0 that B_t is square integrable which allows for the following calculations. For $0\le r_1<\cdots\le r_n\le s$ and some continuous bounded function $f:\mathbb{R}^n\to\mathbb{R}$, by (4.37)

$$\begin{aligned}\big|\mathbf{E}[(B_t-B_s)\cdot f(B_{r_1},\dots,B_{r_n})]\big| &= \lim_{\varepsilon\to\infty}\big|\mathbf{E}[(B_\varepsilon(t)-B_\varepsilon(s))\cdot f(B_\varepsilon(r_1),\dots,B_\varepsilon(r_n))]\big|\\ &\le \lim_{\varepsilon\to\infty}\mathbf{E}\Big[\Big|\mathbf{E}[B_\varepsilon(t)-B_\varepsilon(s)|\mathcal{F}_s]\Big|\cdot f(B_\varepsilon(r_1),\dots,B_\varepsilon(r_n))\Big]=0.\end{aligned}\tag{4.42}$$

Since $r_1,\dots,r_n$ and f were arbitrary, $\mathcal{B}$ is a martingale. Similarly, by (4.40),

$$\begin{aligned}&\big|\mathbf{E}[((B_t-B_s)^2-(t-s))\cdot f(B_{r_1},\dots,B_{r_n})]\big|\\ &\quad=\lim_{\varepsilon\to\infty}\big|\mathbf{E}[((B_\varepsilon(t)-B_\varepsilon(s))^2-(t-s))\cdot f(B_\varepsilon(r_1),\dots,B_\varepsilon(r_n))]\big|\\ &\quad\le\lim_{\varepsilon\to\infty}\mathbf{E}\Big[\Big|\mathbf{E}[(B_\varepsilon(t)-B_\varepsilon(s))^2-(t-s)|\mathcal{F}_s]\Big|\cdot f(B_\varepsilon(r_1),\dots,B_\varepsilon(r_n))\Big]=0,\end{aligned}\tag{4.43}$$

which shows that $(B_t^2-t)_{t\ge 0}$ is a martingale. Then by Lévy's characterization of Brownian motion, $\mathcal{B}$ is a Brownian motion.

5 Preparation: Computing moments of Ψ_λ^{12} and $\widehat{\Psi}_\lambda^{12}$

The key to the proofs of Proposition 3.3 and Theorems 3, 4, 5 and 6 is a proper understanding of the behavior of the functions $\Psi_\lambda^{12}(X_t)$ and $\widehat{\Psi}_\lambda^{12}(X_t)$ from Remark 2.5 along the paths of the tree-valued Fleming–Viot dynamics. In this section, we provide useful tools for the analysis of these functions. In particular, we are going to compute moments up to fourth order.

Throughout this section we assume that

$$\mathcal{X} = (X_t)_{t\geq 0} \text{ is the neutral tree-valued Fleming–Viot equilibrium process,} \tag{5.1}$$

i.e. with $X_0 \overset{d}{=} X_\infty$, and denote by $(\mathcal{F}_t)_{t\geq 0}$ the canonical filtration of $\mathcal{X}$. Furthermore, for the mutation operator, we will assume throughout this section that

$$\beta(u,\cdot) \quad \text{is non-atomic for all} \quad u \in A. \tag{5.2}$$

This assumption implies that every mutation event leads to a new type. In particular, this will be crucial in Lemma 5.8.

5.1 Results on moments of $\Psi_\lambda^{12}(X_t), \widehat{\Psi}_\lambda^{12}(X_t)$ and its increments

The key is to obtain the power at which Ψ_λ^{12} vanishes as $\lambda \to \infty$ respectively at which order $t \mapsto ((\lambda+1)\Psi_\lambda^{12}(X_t) - 1)$ vanishes as $t \to 0$. Proofs of the next two lemmata are given in Section 5.3.

Lemma 5.1 (Convergence for fixed times)**.**
For all $t \geq 0$,

$$\begin{aligned} (\lambda+1)\Psi_\lambda^{12}(X_t) &\xrightarrow{\lambda\to\infty} 1, \\ (\lambda+2\vartheta+1)\widehat{\Psi}_\lambda^{12}(X_t) &\xrightarrow{\lambda\to\infty} 1 \end{aligned} \tag{5.3}$$

in L^2 (and therefore also in probability).

Lemma 5.2 (Second moment of increments of $t \mapsto ((\lambda+1)\Psi_\lambda^{12}(X_t))$)**.**
There exists $C > 0$, which is independent of λ, such that

$$\sup_{\lambda>0} (\lambda+1)^2 \mathbf{E}[(\Psi_\lambda^{12}(X_t) - \Psi_\lambda^{12}(X_0))^2] \leq Ct, \tag{5.4}$$

$$\sup_{\lambda>0} (\lambda+2\vartheta+1)^2 \mathbf{E}[(\widehat{\Psi}_\lambda^{12}(X_t) - \widehat{\Psi}_\lambda^{12}(X_0))^2] \leq Ct. \tag{5.5}$$

Remark 5.3 (Tightness)**.**
If the right hand side of (5.4) would have been $Ct^{1+\varepsilon}$ for some $\varepsilon > 0$, then Lemma 5.2 would imply the needed tightness for Theorem 3 by the Kolmogorov–Chentsov tightness criterion; see e.g. [Kal02, Corollary 14.9]. However, since it is only linear in t, we will have to use fourth moments to get the desired tightness property.

The main goal of this subsection is therefore to compute the fourth moments of the increments of $t \mapsto (\lambda+1)\Psi^{12}(X_t)$ and of $t \mapsto (\lambda+2\vartheta+1)\widehat{\Psi}^{12}(X_t)$. The proof of the next two results are given in Sections 5.5 and 5.6.

Lemma 5.4 (A fourth moment of X_∞)**.**
Let X_∞ be the Kingman measure tree. Then, as $\lambda \to \infty$,

$$\mathbf{E}\big[\big((\lambda+1)\Psi_\lambda^{12}(X_\infty) - 1\big)^4\big] = \frac{3}{4\lambda^2} + \mathcal{O}\Big(\frac{1}{\lambda^3}\Big), \tag{5.6}$$

$$\mathbf{E}\big[\big((\lambda+2\vartheta+1)\Psi_\lambda^{12}(X_\infty) - 1\big)^4\big] = \frac{3}{4\lambda^2} + \mathcal{O}\Big(\frac{1}{\lambda^3}\Big). \tag{5.7}$$

In particular, the convergences in (5.3) hold in L^4 as well.

Lemma 5.5 (Fourth moment of increment of $t \mapsto ((\lambda+1)\Psi_\lambda^{12}(X_t))$**.**
There exists $C > 0$, such that

$$\begin{aligned} &\sup_{\lambda>0}(\lambda+1)^4\mathbf{E}[(\Psi_\lambda^{12}(X_t)-\Psi_\lambda^{12}(X_0))^4] \le Ct^2, \\ &\sup_{\lambda>0}(\lambda+2\vartheta+1)^4\mathbf{E}[(\widehat{\Psi}_\lambda^{12}(X_t)-\widehat{\Psi}_\lambda^{12}(X_0))^4] \le Ct^2. \end{aligned} \tag{5.8}$$

We start with second moments and afterwards, we provide an automated procedure how to compute higher order moments using Mathematica.

5.2 Moments up to second order

Here, we show that $(\lambda+1)\Psi_\lambda^{12} \xrightarrow{\lambda\to\infty} 1$ and $(\lambda+2\vartheta+1)\widehat{\Psi}_\lambda^{12} \xrightarrow{\lambda\to\infty} 1$ in L^2 (Lemma 5.1) and study the second moments of the increments of $t \mapsto ((\lambda+1)\Psi_\lambda^{12}(X_t)-1)$ (Lemma 5.2). We start by defining some functions which appear in the first and second moment equations for the polynomials Ψ_λ^{12} and $\widehat{\Psi}_\lambda^{12}$ defined in Example 2.5.

Definition 5.6 (Some functions on $\mathbb{U}$)**.**
We define the following functions in Π^1:

$$\begin{aligned} \Psi^{\emptyset}(\overline{(U,r,\mu)}) &:= 1, \\ \Psi_\lambda^{12}(\overline{(U,r,\mu)}) &:= \langle \mu^{\otimes\mathbb{N}}, e^{-\lambda r(u_1,u_2)}\rangle, \\ \Psi_\lambda^{12,12}(\overline{(U,r,\mu)}) &:= \Psi_{2\lambda}^{12}(\overline{(U,r,\mu)}) \\ \Psi_\lambda^{12,23}(\overline{(U,r,\mu)}) &:= \langle \mu^{\otimes\mathbb{N}}, e^{-\lambda(r(u_1,u_2)+r(u_2,u_3))}\rangle, \\ \Psi_\lambda^{12,34}(\overline{(U,r,\mu)}) &:= \langle \mu^{\otimes\mathbb{N}}, e^{-\lambda(r(u_1,u_2)+r(u_3,u_4))}\rangle, \\ \widehat{\Psi}^{\emptyset}(\overline{(U,r,\mu)}) &:= 1, \\ \widehat{\Psi}_\lambda^{12}(\overline{(U,r,\mu)}) &:= \langle \mu^{\otimes\mathbb{N}}, \mathbb{1}_{\{a_1=a_2\}}e^{-\lambda r(u_1,u_2)}\rangle, \\ \widehat{\Psi}_\lambda^{12,12}(\overline{(U,r,\mu)}) &:= \widehat{\Psi}_{2\lambda}^{12}(\overline{(U,r,\mu)}), \\ \widehat{\Psi}_\lambda^{12,23}(\overline{(U,r,\mu)}) &:= \langle \mu^{\otimes\mathbb{N}}, \mathbb{1}_{\{a_1=a_2\}}\mathbb{1}_{\{a_2=a_3\}}e^{-\lambda(r(u_1,u_2)+r(u_2,u_3))}\rangle, \\ \Psi_\lambda^{12,34}(\overline{(U,r,\mu)}) &:= \langle \mu^{\otimes\mathbb{N}}, \mathbb{1}_{\{a_1=a_2\}}\mathbb{1}_{\{a_3=a_4\}}e^{-\lambda(r(u_1,u_2)+r(u_3,u_4))}\rangle \end{aligned} \tag{5.9}$$

and centering around the equilibrium expectations

$$\begin{aligned} \Upsilon_\lambda^{12} &:= \Psi_\lambda^{12} - \frac{1}{\lambda+1}, \\ \Upsilon_\lambda^{12,12} &:= \Upsilon_{2\lambda}^{12}, \\ \Upsilon_\lambda^{12,23} &:= \Psi_\lambda^{12,23} - \frac{1}{2}\Psi_{2\lambda}^{12} - \frac{2}{\lambda+2}\Psi_\lambda^{12} + \frac{\lambda+6}{2(\lambda+2)(2\lambda+3)}, \\ \Upsilon_\lambda^{12,34} &:= \Psi_\lambda^{12,34} - \frac{4}{3}\Psi_\lambda^{12,23} + \frac{4}{15}\Psi_{2\lambda}^{12} + \frac{2}{3(\lambda+5)}\Psi_\lambda^{12} - \frac{2\lambda+15}{15(\lambda+3)(\lambda+5)}, \\ \widehat{\Upsilon}_\lambda^{12} &:= \Psi_\lambda^{12} - \frac{1}{\lambda+2\vartheta+1}, \\ \widehat{\Upsilon}_\lambda^{12,12} &:= \widehat{\Upsilon}_{2\lambda}^{12}, \\ \widehat{\Upsilon}_\lambda^{12,23} &:= \widehat{\Psi}_\lambda^{12,23} - \frac{1}{2+\vartheta}\widehat{\Psi}_{2\lambda}^{12} - \frac{2}{\lambda+2\vartheta+2}\widehat{\Psi}_\lambda^{12} \\ &\qquad + \frac{\lambda+3\vartheta+6}{(\vartheta+2)(\lambda+\vartheta+2)(2\lambda+3\vartheta+3)}, \\ \widehat{\Upsilon}_\lambda^{12,34} &:= \widehat{\Psi}_\lambda^{12,34} - \frac{4}{\vartheta+3}\widehat{\Psi}_\lambda^{12,23} + \frac{4}{(\vartheta+3)(2\vartheta+5)}\widehat{\Psi}_{2\lambda}^{12} + \frac{2(1-\vartheta)}{(3+\vartheta)(\lambda+2\vartheta+5)}\widehat{\Psi}_\lambda^{12} \\ &\qquad - \frac{2\lambda+\vartheta-2\vartheta^2+15}{(\vartheta+3)(2\vartheta+5)(\lambda+2\vartheta+3)(\lambda+2\vartheta+5)}. \end{aligned} \tag{5.10}$$

Remark 5.7 (Connections and a first moment)**.**
Our main object of study are the functions Ψ_λ^{12} and $\widehat{\Psi}_\lambda^{12}$. Note that since X_0 has the same law as X_∞ and since in X_∞ the time it takes that two randomly chosen lines coalesce is an exponential random variable R with parameter 1, we have

$$\mathbf{E}[\Psi_\lambda^{12}(\mathcal{U}_0)] = \mathbf{E}[\langle \mu^{\otimes\mathbb{N}}, e^{-\lambda r(u_1,u_2)}\rangle] = \mathbf{E}[e^{-\lambda R}] = \frac{1}{\lambda+1}. \tag{5.11}$$

Moreover, if mutations arise at constant rate $\vartheta/2 > 0$, consider again two randomly chosen lines which coalesce at time R, and the first mutation event at an independent, exponentially distributed time S with rate ϑ, using (5.2):

$$\begin{aligned}\mathbf{E}[\widehat{\Psi}_\lambda^{12}(\mathcal{U}_0)] &= \mathbf{E}[\langle \mu^{\otimes\mathbb{N}}, \mathbb{1}_{\{a_1=a_2\}} e^{-\lambda r(u_1,u_2)}\rangle] = \mathbf{E}[e^{-\lambda R}\mathbb{1}_{\{R\le S\}}] \\ &= \mathbf{E}[e^{-\lambda R}\cdot \mathbf{P}(S\ge R|R)] = \mathbf{E}[e^{-(\lambda+\vartheta)R}] = \frac{1}{\lambda+\vartheta+1}.\end{aligned} \tag{5.12}$$

Moreover, we write

$$\begin{aligned}\Big(\Psi_\lambda^{12}(\overline{(U,r,\mu)})\Big)\cdot\Big(\Psi_\lambda^{12}(\overline{(U,r,\mu)})\Big) &= \langle \mu^{\otimes\mathbb{N}}, e^{-\lambda r(u_1,u_2)}\rangle \cdot \langle \mu^{\otimes\mathbb{N}}, e^{-\lambda r(u_1,u_2)}\rangle \\ &= \langle \mu^{\otimes\mathbb{N}}, e^{-\lambda (r(u_1,u_2)+r(u_3,u_4))}\rangle = \Psi_\lambda^{12,34}(\overline{(U,r,\mu)})\end{aligned} \tag{5.13}$$

and analogously for $\widehat{\Psi}_\lambda^{12,34}$.

Next we compute the action of the generator of $\mathcal{X}$ on the functions from Definition 5.6.

Lemma 5.8 ($\Omega\Psi_\lambda$ and $\Omega\Upsilon_\lambda$)**.**
1. Let Ω be the generator of the tree-valued Fleming–Viot dynamics. Then

$$\begin{aligned}\Omega\Psi_\lambda^{12} &= -(\lambda+1)\Psi_\lambda^{12} + 1\cdot\Psi_\lambda^{\emptyset}, \\ \Omega\Psi_\lambda^{12,23} &= -(2\lambda+3)\Psi_\lambda^{12,23} + 2\Psi_\lambda^{12} + \Psi_{2\lambda}^{12}, \\ \Omega\Psi_\lambda^{12,34} &= -(2\lambda+6)\Psi_\lambda^{12,34} + 4\Psi_\lambda^{12,23} + 2\Psi_\lambda^{12}, \\ \Omega\Upsilon_\lambda^{12} &= -(\lambda+1)\Upsilon_\lambda^{12}, \\ \Omega\Upsilon_\lambda^{12,23} &= -(2\lambda+3)\Upsilon_\lambda^{12,23}, \\ \Omega\Upsilon_\lambda^{12,34} &= -(2\lambda+6)\Upsilon_\lambda^{12,34},\end{aligned} \tag{5.14}$$

and

$$\begin{aligned}\Omega\widehat{\Psi}_\lambda^{12} &= -(\lambda+2\vartheta+1)\widehat{\Psi}_\lambda^{12} + 1\cdot\Psi_\lambda^{\emptyset}, \\ \Omega\widehat{\Psi}_\lambda^{12,23} &= -(2\lambda+3\vartheta+3)\widehat{\Psi}_\lambda^{12,23} + 4\widehat{\Psi}_\lambda^{12}, \\ \Omega\widehat{\Psi}_\lambda^{12,34} &= -(2\lambda+4\vartheta+6)\widehat{\Psi}_\lambda^{12,34} + 4\widehat{\Psi}_\lambda^{12,23} + 2\widehat{\Psi}_\lambda^{12}, \\ \Omega\widehat{\Upsilon}_\lambda^{12} &= -(\lambda+\vartheta+1)\widehat{\Upsilon}_\lambda^{12}, \\ \Omega\widehat{\Upsilon}_\lambda^{12,23} &= -(2\lambda+3\vartheta+3)\widehat{\Upsilon}_\lambda^{12,23}, \\ \Omega\widehat{\Upsilon}_\lambda^{12,34} &= -(2\lambda+4\vartheta+6)\widehat{\Upsilon}_\lambda^{12,34}.\end{aligned} \tag{5.15}$$

2. The following processes of evaluations of functionals of $\mathcal{X} = (X_t)_{t\ge0}$ are martingales:

$$\big(e^{(\lambda+1)t}\Upsilon_\lambda^{12}(X_t)\big)_{t\ge0},\ \big(e^{(2\lambda+3)t}\Upsilon_\lambda^{12,23}(X_t)\big)_{t\ge0},\ \big(e^{(2\lambda+6)t}\Upsilon_\lambda^{12,34}(X_t)\big)_{t\ge0}, \tag{5.16}$$

and

$$\big(e^{(\lambda+2\vartheta+1)t}\widehat{\Upsilon}_\lambda^{12}(X_t)\big)_{t\ge0},\ \big(e^{(2\lambda+3\vartheta+3)t}\widehat{\Upsilon}_\lambda^{12,23}(X_t)\big)_{t\ge0},\ \big(e^{(2\lambda+4\vartheta+6)t}\widehat{\Upsilon}_\lambda^{12,34}(X_t)\big)_{t\ge0}. \tag{5.17}$$

Furthermore for all $s\ge0$ and all $k\in\{12;12,23;12,34\}$

$$\mathbf{E}[\Upsilon_\lambda^k(X_s)] = \mathbf{E}[\widehat{\Upsilon}_\lambda^k(X_s)] = 0. \tag{5.18}$$

Remark 5.9 (Equilibrium expectations of $\Psi^k_\lambda, \widehat{\Psi}^k_\lambda$)**.**
Since $\mathbf{E}[\Upsilon^k_\lambda(X_\infty)] = \mathbf{E}[\widehat{\Upsilon}^k_\lambda(X_\infty)] = 0$ by (5.18), it is also possible to compute the equilibrium values for Ψ^k_λ and $\widehat{\Psi}^k_\lambda$. We write for later reference,

$$\begin{aligned}
\Upsilon^{12,23}_\lambda &= \Psi^{12,23}_\lambda - \frac{5\lambda+3}{(\lambda+1)(2\lambda+1)(2\lambda+3)} \\
&\qquad\qquad - \frac{1}{2}\Big(\Psi^{12}_{2\lambda} - \frac{1}{2\lambda+1}\Big) - \frac{2}{\lambda+2}\Big(\Psi^{12}_\lambda - \frac{1}{\lambda+1}\Big), \\
\Upsilon^{12,34}_\lambda &= \Psi^{12,34}_\lambda - \frac{4\lambda^2+18\lambda+9}{(\lambda+1)(\lambda+3)(2\lambda+1)(2\lambda+3)} \\
&\quad - \frac{4}{3}\Big(\Psi^{12,23}_\lambda - \frac{5\lambda+3}{(\lambda+1)(2\lambda+1)(2\lambda+3)}\Big) \\
&\qquad + \frac{4}{15}\Big(\Psi^{12}_{2\lambda} - \frac{1}{2\lambda+1}\Big) + \frac{2}{3(\lambda+5)}\Big(\Psi^{12}_\lambda - \frac{1}{\lambda+1}\Big)
\end{aligned} \tag{5.19}$$

and

$$\begin{aligned}
\widehat{\Upsilon}^{12,23}_\lambda &= \widehat{\Psi}^{12,23}_\lambda - \frac{5\lambda+6\vartheta+3}{(\lambda+2\vartheta+1)(2\lambda+2\vartheta+1)(2\lambda+3\vartheta+3)} \\
&\quad - \frac{1}{\vartheta+2}\Big(\widehat{\Psi}^{12}_{2\lambda} - \frac{1}{2\lambda+2\vartheta+1}\Big) - \frac{2}{\lambda+\vartheta+2}\Big(\widehat{\Psi}^{12}_\lambda - \frac{1}{\lambda+2\vartheta+1}\Big), \\
\widehat{\Upsilon}^{12,34}_\lambda &= \widehat{\Psi}^{12,34}_\lambda - \frac{4\lambda^2+2\lambda(5\vartheta+9)+21\vartheta+6\vartheta^2+9}{(\lambda+2\vartheta+1)(\lambda+2\vartheta+3)(2\lambda+2\vartheta+1)(2\lambda+3\vartheta+3)} \\
&\quad - \frac{4}{3+\vartheta}\Big(\widehat{\Psi}^{12,23}_\lambda - \frac{5\lambda+6\vartheta+3}{(\lambda+2\vartheta+1)(2\lambda+2\vartheta+1)(2\lambda+3\vartheta+3)}\Big) \\
&\qquad + \frac{4}{(\vartheta+3)(2\vartheta+5)}\Big(\widehat{\Psi}^{12}_{2\lambda} - \frac{1}{2\lambda+2\vartheta+1}\Big) \\
&\qquad\quad + \frac{2(1-\vartheta)}{(\vartheta+3)(\lambda+2\vartheta+5)}\Big(\widehat{\Psi}^{12}_\lambda - \frac{1}{\lambda+2\vartheta+1}\Big)
\end{aligned} \tag{5.20}$$

where the terms after each Ψ^k_λ and $\widehat{\Psi}^k_\lambda$ are the corresponding equilibrium values.

5.3 Proofs of Lemmata 5.1, 5.2 and 5.8

Proof of Lemma 5.8. The results in (5.14) and (5.15) follow by simple calculations. The stated martingale properties are consequences of general theory; see Lemma 4.3.2 in [EK86]. In particular, since the equilibrium distribution of $\mathcal{X}$ is ergodic, for $k \in \{12; 12,23; 12,34\}$ and $\lambda_{12} = \lambda+1, \lambda_{12,23} = 2\lambda+3, \lambda_{12,34} = 2\lambda+6$,

$$\mathbf{E}[\Upsilon^k_\lambda(X_s)] = \lim_{t\to\infty} \mathbf{E}[\Upsilon^k_\lambda(X_t)] = \lim_{t\to\infty} e^{-\lambda_k(t-s)}\mathbf{E}[\Upsilon^k_\lambda(X_s)] = 0 \cdot \mathbf{E}[\Upsilon^k_\lambda(X_s)], \tag{5.21}$$

which can only hold (note that $|\mathbf{E}[\Upsilon^k_\lambda(X_s)]| < \infty$ by definition) if $\mathbf{E}[\Upsilon^k_\lambda(X_s)] = 0$. Replacing λ_k by $\widehat{\lambda}_k$, $\widehat{\lambda}_{12} = \lambda+2\vartheta+1, \widehat{\lambda}_{12,23} = 2\lambda+3\vartheta+3, \widehat{\lambda}_{12,34} = 2\lambda+4\vartheta+6$ gives the corresponding results for the expectations of $\widehat{\Upsilon}^k_\lambda$. ☐

Proof of Lemma 5.1. We only give the full proof for the first assertion in (5.3) since the second follows exactly along the same lines. The proof amounts to computing the variance of Ψ^{12}_λ. Therefore, we need to understand the expectation of $(\Psi^{12}_\lambda)^2 = \Psi^{12,34}_\lambda$ (for the last equality, see (2.6)). To this end we express the Ψ_λ's in term of the Υ_λ's and obtain

$$\begin{aligned}
\Psi_\lambda^{12} &= \Upsilon_\lambda^{12} + \frac{1}{\lambda+1}, \\
\Psi_\lambda^{12,23} &= \Upsilon_\lambda^{12,23} + \frac{1}{2}\Upsilon_\lambda^{12,12} + \frac{2}{2+\lambda}\Upsilon_\lambda^{12} + \frac{5\lambda+3}{(\lambda+1)(2\lambda+1)(2\lambda+3)}, \\
\Psi_\lambda^{12,34} &= \Upsilon_\lambda^{12,34} + \frac{4}{3}\Upsilon_\lambda^{12,23} + \frac{2}{5}\Upsilon_\lambda^{12,12} + \frac{2(\lambda+6)}{(\lambda+2)(\lambda+5)}\Upsilon_\lambda^{12} \\
&\qquad + \frac{4\lambda^2+18\lambda+9}{(\lambda+1)(\lambda+3)(2\lambda+1)(2\lambda+3)}.
\end{aligned} \tag{5.22}$$

Together with (5.18), this implies

$$\begin{aligned}
\mathbf{E}[((\lambda+1)\Psi^{12}(X_t)-1)^2] &= (\lambda+1)^2\cdot\mathbf{E}[\Psi_\lambda^{12,34}(X_t)] - 2(\lambda+1)\cdot\mathbf{E}[\Psi_\lambda^{12}(X_t)] + 1 \\
&= \frac{2\lambda^2}{(\lambda+3)(2\lambda+1)(2\lambda+3)} \xrightarrow{\lambda\to\infty} 0.
\end{aligned} \tag{5.23}$$

□

Proof of Lemma 5.2. Again, we restrict our proof to (5.4) since (5.5) is proved analogously. We compute

$$\begin{aligned}
\mathbf{E}[\Psi_\lambda^{12}(X_0)\Upsilon_\lambda^{12}(X_0)] &= \mathbf{E}\Big[\Psi_\lambda^{12,34}(X_0) - \frac{1}{\lambda+1}\Psi_\lambda^{12}(X_0)\Big] \\
&= \frac{2\lambda^2}{(\lambda+1)^2(\lambda+3)(2\lambda+1)(2\lambda+3)}
\end{aligned} \tag{5.24}$$

and (recall that we start in equilibrium)

$$\begin{aligned}
&\mathbf{E}[(\Psi_\lambda^{12}(X_t)-\Psi_\lambda^{12}(X_0))^2] \\
&\qquad = \mathbf{E}[(\Psi_\lambda^{12}(X_t))^2 - (\Psi_\lambda^{12}(X_0))^2 - 2\Psi_\lambda^{12}(X_0)(\Psi_\lambda^{12}(X_t)-\Psi_\lambda^{12}(X_0))] \\
&\qquad = \mathbf{E}\Big[2\Psi_\lambda^{12}(X_0)\int_0^t \Omega\Upsilon_\lambda^{12}(X_s)ds\Big] \\
&\qquad = \int_0^t \mathbf{E}[2\Psi_\lambda^{12}(X_0)(\lambda+1)\mathbf{E}[\Upsilon_\lambda^{12}(X_s)|\mathcal{F}_0]]ds \\
&\qquad = 2\int_0^t (\lambda+1)e^{-(\lambda+1)s}ds\cdot\mathbf{E}[\Psi_\lambda^{12}(X_0)\Upsilon_\lambda^{12}(X_0)] \\
&\qquad \le \frac{4}{(\lambda+1)^2}t
\end{aligned} \tag{5.25}$$

and the result follows. □

5.4 Moments up to fourth order

For the proofs of Lemma 5.4 and Lemma 5.5 we use moment calculations of the increments of $(\Psi_\lambda^{12}(X_t))_{t\ge0}$ and $(\widehat{\Psi}_\lambda^{12}(X_t))_{t\ge0}$ up to fourth order. The calculations are presented in an algorithmic way such that higher moments can be computed along the same lines. The fundamental idea is that all computations that need to be done are *linear maps* on the vector spaces:

$$\begin{aligned}
\mathbb{V}_\lambda &:= \operatorname{span}\big(\{\Psi_\lambda^{\mathcal{I}} : \overline{(U,r,\mu)} \mapsto \langle\mu^{\otimes\mathbb{N}}, \prod_{(i,j)\in\mathcal{I}} e^{-\lambda r(u_i,u_j)}\rangle : \mathcal{I}\text{ finite subset of }\mathbb{N}^2\}\big), \\
\widehat{\mathbb{V}}_\lambda &:= \operatorname{span}\big(\{\widehat{\Psi}_\lambda^{\mathcal{I}} : \overline{(U,r,\mu)} \mapsto \langle\mu^{\otimes\mathbb{N}}, \prod_{(i,j)\in\mathcal{I}} \mathbb{1}_{\{a_i=a_j\}}e^{-\lambda r(u_i,u_j)}\rangle : \mathcal{I}\text{ finite subset of }\mathbb{N}^2\}\big).
\end{aligned} \tag{5.26}$$

We point out that one advantage of using matrix algebra is that it is possible to use computer algebra software such as Mathematica for automated computations.

Apparently, a *basis* of the vector spaces $\mathbb{V}_\lambda$ and $\widehat{\mathbb{V}}_\lambda$ are given by (recall from Definition 5.6)

$$\underline{\Psi}_\lambda \coloneqq (\Psi_\lambda^\emptyset, \Psi_\lambda^{12}, \Psi_\lambda^{12,12}, \Psi_\lambda^{12,23}, \Psi_\lambda^{12,34}, \dots), \tag{5.27}$$

$$\underline{\widehat{\Psi}}_\lambda \coloneqq (\widehat{\Psi}_\lambda^\emptyset, \widehat{\Psi}_\lambda^{12}, \widehat{\Psi}_\lambda^{12,12}, \widehat{\Psi}_\lambda^{12,23}, \widehat{\Psi}_\lambda^{12,34}, \dots), \tag{5.28}$$

respectively. By inspection of e.g. Lemma 5.8 it is clear, that the generator Ω gives rise to linear operators $\mathbb{V}_\lambda \to \mathbb{V}_\lambda$ and $\widehat{\mathbb{V}}_\lambda \to \widehat{\mathbb{V}}_\lambda$. The bases $\underline{\Psi}_\lambda$ and $\underline{\widehat{\Psi}}_\lambda$ can be ordered such that the matrices representing the linear maps Ω on $\mathbb{V}_\lambda$ and $\widehat{\mathbb{V}}_\lambda$ are *upper triangular*; see also Lemma 5.8.

In the next section, we give the action of Ω on the first 36 basis vectors for each basis. The last basis vectors in these collections are given by

$$\Psi_\lambda^{12,34,56,78} : \overline{(U, r, \mu)} \mapsto \langle \mu^{\otimes\mathbb{N}}, e^{-\lambda r_{12,34,56,78}} \rangle, \tag{5.29}$$

where we write $r_{12,34,56,78} \coloneqq r(u_1, u_2) + r(u_3, u_4) + r(u_5, u_6) + r(u_7, u_8)$, and

$$\widehat{\Psi}_\lambda^{12,34,56,78} : \overline{(U, r, \mu)} \mapsto \langle \mu^{\otimes\mathbb{N}}, \mathbb{1}_{\{a_1=a_2, a_3=a_4, a_5=a_6, a_7=a_8\}} e^{-\lambda r_{12,34,56,78}} \rangle, \tag{5.30}$$

respectively. Because of $(\Psi_\lambda^{12})^4 = \Psi_\lambda^{12,34,56,78}$ and $(\widehat{\Psi}_\lambda^{12})^4 = \widehat{\Psi}_\lambda^{12,34,56,78}$ both 36's basis elements play important roles.

The matrix representation of the generator Ω

Here, we give the matrix representation of the generator Ω in terms of the basis $\underline{\Psi}_\lambda$, i.e. we find matrices A and $\widehat{A}$ such that

$$\Omega \underline{\Psi}_\lambda^\top = A \underline{\Psi}_\lambda^\top, \qquad \Omega \underline{\widehat{\Psi}}_\lambda^\top = \widehat{A} \underline{\widehat{\Psi}}_\lambda^\top. \tag{5.31}$$

The following list contains the action on the first 36 basis vectors from $\underline{\Psi}_\lambda$ and $\underline{\widehat{\Psi}}_\lambda$.

In 5. as an example (see below) we are dealing with the function

$\Psi_\lambda^{12,34}$(and $\widehat{\Psi}_\lambda^{12,34}$), for which we use  as abbreviation. (5.32)

As this symbol indicates, in $\Psi_\lambda^{12,34}$, two non-overlapping pairs are sampled.

We have already seen in (5.14) that

$$\Omega \Psi_\lambda^{12,34} = -(2\lambda + 6)\Psi_\lambda^{12,34} + 2\Psi_\lambda^{12} + 4\Psi_\lambda^{12,23}, \tag{5.33}$$

$$\Omega \widehat{\Psi}_\lambda^{12,34} = -(2\lambda + 4\vartheta + 6)\widehat{\Psi}_\lambda^{12,34} + 2\widehat{\Psi}_\lambda^{12} + 4\widehat{\Psi}_\lambda^{12,23}. \tag{5.34}$$

Our list only contains the last two terms (which are equal in both equations) which arise from  by merging of a pair of leaves, i.e. merging for example the marked leaves in  to  or merging the marked leaves in  to . The coefficient of $\Psi_\lambda^{12,34}$ in $\Omega\Psi_\lambda^{12,34}$ (and of $\widehat{\Psi}_\lambda^{12,34}$ in $\Omega\widehat{\Psi}_\lambda^{12,34}$) is given such that the sum of coefficients in $\Omega\Psi_\lambda^{12,34}$ equals λ times the number of pairs (i.e. 2) in $\Psi_\lambda^{12,34}$ (and ϑ times the number of different indices (i.e. 4)). Since the table would be the same for the $\widehat{\Psi}_\lambda^k$'s, we restrict ourselves to the Ψ_λ^k's.

35. $\Psi_\lambda^{12,34,56,78} \equiv$ 
For the matrices A (and $\widehat{A}$) representing Ω in terms of the basis $\underline{\Psi}_\lambda$ (and $\underline{\widehat{\Psi}}_\lambda$), we give here only the first 13 (5) rows and columns for A ($\widehat{A}$), which are dealing with samples of at most three (two) pairs (i.e. $|\mathcal{I}| \leq 3$ (≤ 2) in (5.26)). For A, we get

$$-A := \begin{pmatrix}
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
-1 & \lambda+1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
-1 & 0 & 2\lambda+1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 2 & -1 & 2\lambda+3 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 2 & 0 & -4 & 2\lambda+6 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
-1 & 0 & 0 & 0 & 0 & 3\lambda+1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & -1 & -1 & 0 & 0 & -1 & 3\lambda+3 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & -3 & 0 & 0 & 0 & 0 & 3\lambda+3 & 0 & 0 & 0 & 0 & 0 \\
0 & -1 & -1 & 0 & 0 & 0 & -4 & 0 & 3\lambda+6 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & -3 & 0 & 0 & -3 & 0 & 0 & 3\lambda+6 & 0 & 0 & 0 \\
0 & 0 & 0 & -3 & 0 & 0 & -2 & -1 & 0 & 0 & 3\lambda+6 & 0 & 0 \\
0 & 0 & 0 & -1 & -2 & 0 & 0 & 0 & -1 & -2 & -4 & 3\lambda+10 & 0 \\
0 & 0 & 0 & 0 & -3 & 0 & 0 & 0 & 0 & 0 & 0 & -12 & 3\lambda+15
\end{pmatrix}$$

while for $\widehat{A}$ we have

$$-\widehat{A} := \begin{pmatrix}
0 & 0 & 0 & 0 & 0 \\
-1 & \lambda+2\vartheta+1 & 0 & 0 & 0 \\
-1 & 0 & 2\lambda+2\vartheta+1 & 0 & 0 \\
0 & 2 & -1 & 2\lambda+3\vartheta+3 & 0 \\
0 & 2 & 0 & -4 & 2\lambda+4\vartheta+6
\end{pmatrix}$$

Note that both matrices are diagonalisable. The reason is that the submatrix containing the same eigenvalue (take $3\lambda + 6$ in A above as an example) is diagonal. Hence, there are three independent eigenvectors for this eigenvalue and so, we find a basis of eigenvectors.

In the rest of this section, the calculations for the Ψ_λ^k's and $\widehat{\Psi}_\lambda^k$'s are completely analogous using the $\widehat{\Upsilon}_\lambda^k$'s instead of the Υ_λ^k's. Hence, we only present the calculations concerning Ψ_λ^k's.

Conditioning as a linear map

During our calculations, we need to be able to compute terms like $\mathbf{E}\Big[\sum_{k=1}^n a_k \Psi_\lambda^k(X_t)|\mathcal{F}_s\Big]$ for $s \leq t$. We do this using the following procedure. We have given the following objects:

1. A basis
$$\underline{\Upsilon}_\lambda := (\Upsilon_\lambda^\emptyset, \Upsilon_\lambda^{12}, \Upsilon_\lambda^{12,12}, \dots) \tag{5.35}$$
such that $\Omega\Upsilon_\lambda^k = \lambda_k \Upsilon_\lambda^k$, i.e. Υ_λ^k is an eigenvector of the generator Ω for the eigenvalue λ_k (where $k \in \{\emptyset; 12; 12,12; 12,23; 12,34; \dots\}$. As argued below, these eigenvectors exist, since A is diagonalisable.
2. A diagonal matrix D_{t-s} with diagonal entries $e^{-\lambda_k(t-s)}$ in the kth line. Since the λ_k's are given by 1., this matrix is readily obtained.
3. An invertible matrix $M_{\underline{\Psi}_\lambda}^{\underline{\Upsilon}_\lambda} = (M_{\underline{\Upsilon}_\lambda}^{\underline{\Psi}_\lambda})^{-1}$, such that $\underline{\Psi}_\lambda M_{\underline{\Psi}_\lambda}^{\underline{\Upsilon}_\lambda} = \underline{\Upsilon}_\lambda$ and $\underline{\Upsilon}_\lambda M_{\underline{\Upsilon}_\lambda}^{\underline{\Psi}_\lambda} = \underline{\Psi}_\lambda$. These two matrices allow a change of basis from $\underline{\Psi}_\lambda$ to $\underline{\Upsilon}_\lambda$ and back.

   Since $\underline{\Upsilon}_\lambda$ is the basis of eigenvectors of the matrix A, the matrices $M_{\underline{\Psi}_\lambda}^{\underline{\Upsilon}_\lambda}$ and $M_{\underline{\Upsilon}_\lambda}^{\underline{\Psi}_\lambda}$ are obtained by standard linear algebra. We stress that both matrices are lower triangular since A is lower triangular.

Then, because $(e^{\lambda_k t}\Upsilon_\lambda^k(t))_{t\geq 0}$ are martingales, (compare with Lemma 5.8),

$$\begin{aligned}\mathbf{E}\big[\underline{\Psi}_\lambda^\top(X_t)|\mathcal{F}_s\big] &= M_{\underline{\Upsilon}_\lambda}^{\underline{\Psi}_\lambda} \cdot \mathbf{E}[\underline{\Upsilon}_\lambda(X_t)|\mathcal{F}_s]^\top = M_{\underline{\Upsilon}_\lambda}^{\underline{\Psi}_\lambda} \cdot D_{t-s} \cdot \underline{\Upsilon}_\lambda(X_s)^\top \\ &= M_{\underline{\Upsilon}_\lambda}^{\underline{\Psi}_\lambda} \cdot D_{t-s} \cdot M_{\underline{\Psi}_\lambda}^{\underline{\Upsilon}_\lambda} \cdot \underline{\Psi}_\lambda(X_s)^\top.\end{aligned} \tag{5.36}$$

This means that conditioning linear combinations of elements in $\underline{\Psi}_\lambda(X_t)$ on $\mathcal{F}_s$ can be represented by a composition of linear maps.

Multiplication with Ψ_λ^{12} as a linear map

We need to compute the action of multiplying an element of $\mathbb{V}_\lambda$ with Ψ_λ^{12}. Since $\mathbb{V}_\lambda$ is actually an algebra of functions (see Remark 2.5 and Remark 2.8 in [GPW12]), this can be done. We have that

$$\Psi_\lambda^{12}\underline{\Psi}_\lambda^\top = \Big(\Psi_\lambda^{12}, \Psi_\lambda^{12,34}, \Psi_\lambda^{12,12,34}, \Psi^{12,23,45}, \dots). \tag{5.37}$$

This means that there is a linear matrix Q such that

$$\Psi_\lambda^{12}\underline{\Psi}_\lambda^\top = Q\underline{\Psi}_\lambda^\top. \tag{5.38}$$

Apparently, Q is the matrix for a linear map on $\mathbb{V}_\lambda$, with respect to the basis $\underline{\Psi}_\lambda$.

5.5 Proof of Lemma 5.4

Again, we only give the calculations for the Ψ_λ^k's in detail. We use

$$\begin{aligned}((\lambda+1)\Psi_\lambda^{12}-1)^4 = (\lambda+1)^4\Psi_\lambda^{12,34,56,78} - 4(\lambda+1)^3\Psi^{12,34,56} \\ + 6(\lambda+1)^2\Psi_\lambda^{12,34} + 4(\lambda+1)\Psi_\lambda^{12} + 1.\end{aligned} \tag{5.39}$$

By construction, we obtain for all $k \in \mathcal{I}$

$$\mathbf{E}[\Psi_\lambda^k(X_\infty)] = \mathbf{E}[(\underline{\Upsilon}_\lambda(X_\infty)M_{\underline{\Upsilon}_\lambda}^{\Psi_\lambda})_k] = (M_{\underline{\Upsilon}_\lambda}^{\Psi_\lambda})_{\emptyset;k} \tag{5.40}$$

since $\mathbf{E}[\Upsilon_\lambda^k(X_\infty)] = 0$ for $k \neq \emptyset$ as in (5.18). Hence, (for the first two terms, see also (5.22))

$$\begin{aligned}(\lambda+1)\Psi_\lambda^{12}(X_\infty) &= 1, \\ (\lambda+1)^2\Psi_\lambda^{12,34}(X_\infty) &= \frac{4\lambda^4+26\lambda^3+49\lambda^2+36\lambda+9}{4\lambda^4+24\lambda^3+47\lambda^2+36\lambda+9} = 1+\frac{1}{2\lambda}-\frac{5}{2\lambda^2}+\mathcal{O}\Big(\frac{1}{\lambda^3}\Big), \\ (\lambda+1)^3\Psi_\lambda^{12,34,56}(X_\infty) &= \frac{36\lambda^7+618\lambda^6+4143\lambda^5+\mathcal{O}(\lambda^4)}{36\lambda^7+564\lambda^6+3487\lambda^5+\mathcal{O}(\lambda^4)} \\ &= 1+\frac{3}{2\lambda}-\frac{95}{18\lambda^2}+\mathcal{O}\Big(\frac{1}{\lambda^3}\Big), \\ (\lambda+1)^4\Psi_\lambda^{12,34,56,78}(X_\infty) &= \frac{36864\lambda^{16}+1536000\lambda^{15}+28807680\lambda^{14}+\mathcal{O}(\lambda^{13})}{36864\lambda^{16}+1425408\lambda^{15}+24729088\lambda^{14}+\mathcal{O}(\lambda^{13})} \\ &= 1+\frac{3}{\lambda}-\frac{193}{36\lambda^2}+\mathcal{O}\Big(\frac{1}{\lambda^3}\Big).\end{aligned} \tag{5.41}$$

Plugging the last expressions in (5.39) gives the result.

5.6 Proof of Lemma 5.5

Now we can compute the fourth moments of the increments of $t \mapsto (\lambda+1)\Psi^{12}(X_t)$. Again, we only give the proof of the first assertion. The second follows by replacing the Ψ_λ^k's by the $\widehat{\Psi}_\lambda^k$'s. Using Minkowski's inequality and the fact that we start in equilibrium we have

$$\begin{aligned}\big(\mathbf{E}[(\Psi_\lambda^{12}(X_t)-\Psi_\lambda^{12}(X_0))^4]\big)^{1/4} &\leq \big(\mathbf{E}[(\Psi_\lambda^{12}(X_t))^4]\big)^{1/4} + \big(\mathbf{E}[(\Psi_\lambda^{12}(X_0))^4]\big)^{1/4} \\ &= 2\big(\mathbf{E}[\Psi_\lambda^{12,34,56,78}(X_0)]\big)^{1/4}\end{aligned} \tag{5.42}$$

and therefore, since $\mathbf{E}[\Psi_\lambda^{12,34,56,78}(X_0)] = \mathcal{O}(\lambda^{-4})$ as $\lambda \to \infty$ by (5.41), we have

$$(\lambda+1)^4\mathbf{E}[(\Psi_\lambda^{12}(X_t)-\Psi_\lambda^{12}(X_0))^4] \leq 2^4(\lambda+1)^4\mathbf{E}[\Psi_\lambda^{12,34,56,78}(X_0)] = \mathcal{O}(1). \tag{5.43}$$

Thus, the expression on the left hand side of (5.8) is *bounded*.

Now, using

$$(a-b)^4 = a^4 - b^4 - 4b(a^3-b^3) + 6b^2(a^2-b^2) - 4b^3(a-b) \tag{5.44}$$

we obtain,

$$\begin{aligned}
&\mathbf{E}[(\Psi_\lambda^{12}(X_t)-\Psi_\lambda^{12}(X_0))^4] \\
&\quad= \mathbf{E}[\Psi_\lambda^{12,34,56,78}(X_t)-\Psi_\lambda^{12,34,56,78}(X_0)] \\
&\qquad\qquad - 4\mathbf{E}\big[\Psi_\lambda^{12}(X_0)\big(\Psi_\lambda^{12,34,56}(X_t)-\Psi_\lambda^{12,34,56}(X_0)\big)\big] \\
&\qquad\qquad\qquad + 6\mathbf{E}\big[\Psi_\lambda^{12,34}(X_0)\big(\Psi_\lambda^{12,34}(X_t)-\Psi_\lambda^{12,34}(X_0)\big)\big] \\
&\qquad\qquad\qquad\qquad - 4\mathbf{E}[\Psi_\lambda^{12,34,56}(X_0)\big(\Psi_\lambda^{12}(X_t)-\Psi_\lambda^{12}(X_0)\big)\big] \\
&\quad= -4\int_0^t \mathbf{E}[\Psi_\lambda^{12}(X_0)\Omega\Psi_\lambda^{12,34,56}(X_s)]ds + 6\int_0^t \mathbf{E}[\Psi_\lambda^{12,34}(X_0)\Omega\Psi_\lambda^{12,34}(X_s)]ds \\
&\qquad\qquad\qquad\qquad - 4\int_0^t \mathbf{E}[\Psi_\lambda^{12,34,56}(X_0)\Omega\Psi_\lambda^{12}(X_s)]ds,
\end{aligned} \tag{5.45}$$

because $\Psi_\lambda^{12,34,56,78}(X_t) \overset{d}{=} \Psi_\lambda^{12,34,56,78}(X_0)$, since we start in equilibrium.

Let us consider the expectation in the second term on the right hand side. We have

$$\begin{aligned}
\mathbf{E}[\Psi_\lambda^{12,34}(X_0)\Omega\Psi_\lambda^{12,34}(X_s)] &= \mathbf{E}[\Psi_\lambda^{12,34}(X_0)\mathbf{E}[\Omega\Psi_\lambda^{12,34}(X_s)|\mathcal{F}_0]] \\
&= \mathbf{E}[\Psi_\lambda^{12,34}(X_0)\big(A\cdot\mathbf{E}[\underline{\Psi}_\lambda(X_s)|\mathcal{F}_0]\big)_{12,34}] \\
&= \mathbf{E}[\Psi_\lambda^{12,34}(X_0)\big(A\cdot M_{\underline{\Upsilon}_\lambda}^{\underline{\Psi}_\lambda}\mathbf{E}[\underline{\Upsilon}_\lambda(X_s)|\mathcal{F}_0]\big)_{12,34}] \\
&= \mathbf{E}[\Psi_\lambda^{12,34}(X_0)\big(A\cdot M_{\underline{\Upsilon}_\lambda}^{\underline{\Psi}_\lambda}D_sM_{\underline{\Psi}_\lambda}^{\underline{\Upsilon}_\lambda}\underline{\Psi}_\lambda(X_0)\big)_{12,34}] \\
&= \mathbf{E}[\Psi_\lambda^{12}(X_0)\big(A\cdot M_{\underline{\Upsilon}_\lambda}^{\underline{\Psi}_\lambda}D_sM_{\underline{\Psi}_\lambda}^{\underline{\Upsilon}_\lambda}Q\underline{\Psi}_\lambda(X_0)\big)_{12,34}] \\
&= \mathbf{E}[\big(A\cdot M_{\underline{\Upsilon}_\lambda}^{\underline{\Psi}_\lambda}D_sM_{\underline{\Psi}_\lambda}^{\underline{\Upsilon}_\lambda}QQ\underline{\Psi}_\lambda(X_0)\big)_{12,34}].
\end{aligned} \tag{5.46}$$

The expression in the last line can easily be integrated in s over $[0,t]$, because only D_s depends on s. In addition, X_0 is in equilibrium and hence, the expectation can be evaluated using the equilibrium distribution of $\mathcal{X}$. All three terms in the right hand side of (5.45) can be computed analogously. Using Mathematica, we see that (5.8) holds.

6 Proof of Lemma 3.4, Propositions 3.3 and 3.6 and Theorems 3 and 4

6.1 Proof of Proposition 3.3

By Lemma 3.4 we have to show that (3.7) holds. Recall Ψ_λ^{12} from (4.14). We abbreviate $\Psi_\lambda^{12} := \Psi_\lambda^{12}(X_\infty)$ and compute, using Lemma 5.4

$$\lambda^2\mathbf{E}\big[\big((\lambda+1)\Psi_\lambda^{12}-1\big)^4\big] \xrightarrow{\lambda\to\infty} \frac{3}{4}. \tag{6.1}$$

Therefore, there is $C>0$, such that

$$\mathbf{P}(|(\lambda+1)\Psi_\lambda^{12}-1|>\varepsilon) \le \frac{\mathbf{E}[(\lambda+1)\Psi_\lambda^{12}-1)^4]}{\varepsilon^4} \le \frac{C}{\varepsilon^4\lambda^2}. \tag{6.2}$$

It follows that almost surely $|(n+1)\Psi_n^{12}-1|>\varepsilon$ for at most finitely many n by the Borel–Cantelli lemma. Thus,

$$1 = \lim_{\lambda\to\infty}\lfloor\lambda\rfloor\Psi_{\lceil\lambda\rceil}^{12} \le \liminf_{\lambda\to\infty}(\lambda+1)\Psi_\lambda^{12} \le \limsup_{\lambda\to\infty}(\lambda+1)\Psi_\lambda^{12} \le \lim_{\lambda\to\infty}\lceil\lambda+1\rceil\Psi_{\lfloor\lambda\rfloor}^{12} = 1 \tag{6.3}$$

holds almost surely and the result is shown.

6.2 Proof of Lemma 3.4

Recall that (3.7) is the short form of

$$(\lambda+1)\int \mu_\infty^{\otimes 2}(d(u_1,u_2))e^{-\lambda r(u_1,u_2)} \xrightarrow{\lambda\to\infty} 1. \tag{6.4}$$

Furthermore, since $F_i(2\varepsilon)$ is the probability of sampling a leaf from $B_i(2\varepsilon)$ under the sampling measure (and hence, $F_i(2\varepsilon)^2$ is the probability of picking two leaves from $B_i(2\varepsilon)$), for every realisation of N_ε, F_i and μ_∞ we have

$$\frac{1}{\varepsilon}\sum_{i=1}^{N_\varepsilon} F_i(2\varepsilon)^2 = \frac{1}{2\varepsilon}\int \mu_\infty^{\otimes 2}(d(u_1,u_2))\mathbb{1}_{\{r(u_1,u_2)\le 2\varepsilon\}} = \frac{1}{2\varepsilon}\nu[0,2\varepsilon]. \tag{6.5}$$

Here we set $\nu := r(\cdot,\cdot)_*\mu_\infty^{\otimes 2}$, i.e. the distribution of the distance of two randomly chosen leaves. Thus, the assertion of Lemma 3.4 is the equivalence of $\lambda\int e^{-\lambda x}\nu(dx) \xrightarrow{\lambda\to\infty} 1$ and $\frac{1}{\varepsilon}\nu[0,\varepsilon] \xrightarrow{\varepsilon\to 0} 1$. This equivalence is implied by classical Tauberian Theorems, as e.g. given in Theorem 3, Chapter XIII.5 of [Fel66].

6.3 Proof of Proposition 3.6

We proceed in three steps.

- **Step 1:** Tightness of one-dimensional distributions of $\mathcal{Z}^\lambda$.
- **Step 2:** Moments and covariance structure.
- **Step 3:** Tightness of $\mathcal{Z}^\lambda$ in path-space (in the space of continuous functions).

Step 1: Tightness of one-dimensional distributions of $\mathcal{Z}^\lambda$*.* We obtain from Remark 5.9,

$$\mathbf{E}[(Z_t^\lambda)^2] = \lambda\mathbf{E}[(\lambda t+1)^2\Psi_{\lambda t}^{12,34} - 2(\lambda t+1)\Psi_{\lambda t}^{12} + 1] \xrightarrow{\lambda\to\infty} \frac{1}{2t}, \tag{6.6}$$

which shows the claimed tightness.

Step 2: Moments and covariance structure. For the covariance structure, we have to compute moments of $\Psi_{s\lambda}^{12}\Psi_{t\lambda}^{12}$ which are not included in the manuscript up to here. We set

$$\begin{aligned}
\Psi_{\lambda,\lambda'}^{12,23}(\overline{(U,r,\mu)}) &:= \langle \mu^{\otimes\mathbb{N}}, e^{-\lambda r(u_1,u_2)-\lambda' r(u_2,u_3)}\rangle,\\
\Psi_{\lambda,\lambda'}^{12,34}(\overline{(U,r,\mu)}) &:= \langle \mu^{\otimes\mathbb{N}}, e^{-\lambda r(u_1,u_2)-\lambda' r(u_3,u_4)}\rangle,\\
\Upsilon_\lambda^{12} &:= \Psi_\lambda^{12} - \frac{1}{\lambda+1},\\
\Upsilon_{\lambda,\lambda'}^{12,23} &:= \Psi_{\lambda,\lambda'}^{12,23} - \frac{1}{2}\Psi_{\lambda+\lambda'}^{12} - \frac{1}{\lambda+2}\Psi_\lambda^{12} - \frac{1}{\lambda'+2}\Psi_{\lambda'}^{12}\\
&\qquad + \frac{\lambda\lambda'+4\lambda+4\lambda'+12}{2(\lambda+2)(\lambda'+2)(\lambda+\lambda'+3)},\\
\Upsilon_{\lambda,\lambda'}^{12,34} &:= \Psi_{\lambda,\lambda'}^{12,34} - \frac{4}{3}\Psi_{\lambda,\lambda'}^{12,23} + \frac{4}{15}\Psi_{\lambda+\lambda'}^{12} + \frac{1}{3(\lambda+5)}\Psi_\lambda^{12} + \frac{1}{3(\lambda'+5)}\Psi_{\lambda'}^{12}\\
&\qquad - \frac{4\lambda\lambda'+25\lambda+25\lambda'+150}{15(\lambda+5)(\lambda'+5)(\lambda+\lambda'+6)}.
\end{aligned} \tag{6.7}$$

Then

$$\begin{aligned}
\Omega\Psi^{12,23}_{\lambda,\lambda'} &= -(\lambda+\lambda'+3)\Psi^{12,23}_{\lambda,\lambda'} + \Psi^{12}_{\lambda} + \Psi^{12}_{\lambda'} + \Psi^{12}_{\lambda+\lambda'},\\
\Omega\Psi^{12,34}_{\lambda,\lambda'} &= -(\lambda+\lambda'+6)\Psi^{12,34}_{\lambda,\lambda'} + 4\Psi^{12,23}_{\lambda,\lambda'} + \Psi^{12}_{\lambda} + \Psi^{12}_{\lambda'},\\
\Omega\Upsilon^{12}_{\lambda} &= -(\lambda+1)\Upsilon^{12}_{\lambda},\\
\Omega\Upsilon^{12,23}_{\lambda,\lambda'} &= -(\lambda+\lambda'+3)\Upsilon^{12,23}_{\lambda,\lambda'},\\
\Omega\Upsilon^{12,34}_{\lambda,\lambda'} &= -(\lambda+\lambda'+6)\Upsilon^{12,34}_{\lambda,\lambda'}.
\end{aligned} \tag{6.8}$$

Now, in order to compute the covariance structure and higher moments, we write, again using Mathematica,

$$\begin{aligned}
\mathbf{E}[Z^\lambda_s Z^\lambda_t] &= \lambda \mathbf{E}[(s\lambda+1)(t\lambda+1)\Psi^{12,34}_{s\lambda,t\lambda} - 1]\\
&= \frac{4st\lambda^3}{((s+t)\lambda+1)((s+t)\lambda+3)((s+t)\lambda+6)}\\
&\xrightarrow{\lambda\to\infty} \frac{4st}{(s+t)^3}.
\end{aligned} \tag{6.9}$$

For the third moment,

$$\mathbf{E}[(Z^\lambda_t)^3] = \lambda^{3/2}\frac{16t^3\lambda^3(5t^2\lambda^2+9t\lambda-10)}{(t\lambda+2)(t\lambda+3)(t\lambda+5)(2t\lambda+1)(2t\lambda+3)(3t\lambda+1)(3t\lambda+10)} \xrightarrow{\lambda\to\infty} 0. \tag{6.10}$$

The fourth moment was already given in (6.1).

Step 3: Tightness of $\mathcal{Z}^\lambda$ in path-space. Here, we show that there exists $C > 0$, which is independent of λ, such that

$$\sup_{\lambda>0} \lambda \cdot \mathbf{E}[((t\lambda+1)\Psi^{12}_{t\lambda}(X_\infty) - (s\lambda+1)\Psi^{12}_{s\lambda}(X_\infty))^2] \le C(t-s)^2 \tag{6.11}$$

for $0 < s \le t$. Tightness then follows from Step 1 and the Kolmogorov–Chentsov criterion. In order to show (6.11), we simplify the notation and suppress the dependency on X_∞. From (6.7), we read off $\mathbf{E}[\Psi^{12,34}_{s\lambda,t\lambda}]$. Then, the result follows from

$$\begin{aligned}
&((t\lambda+1)\Psi^{12}_{t\lambda} - (s\lambda+1)\Psi^{12}_{s\lambda})^2\\
&\qquad = (t\lambda+1)^2\Psi^{12,34}_{t\lambda,t\lambda} - 2(s\lambda+1)(t\lambda+1)\Psi^{12,34}_{s\lambda,t\lambda} + (s\lambda+1)^2\Psi^{12,34}_{s\lambda,s\lambda},
\end{aligned} \tag{6.12}$$

with an application of Mathematica and (6.11) is shown.

6.4 Proof of Theorem 3

As in the proof of Theorem 1, we only need to show the assertion in the case $\alpha = 0$ due to absolute continuity recalled in Proposition 2.11. In this case, the proof of the theorem requires the following three steps:

- **Step 1:** Instead of starting in $\mathcal{X}_0$, it suffices to start in equilibrium and then show (3.23).
- **Step 2:** Assume that $\mathcal{X}_0$ is in equilibrium, i.e. $X_0 \overset{d}{=} X_\infty$. Then, the set of processes
$$\{((\lambda+1)\Psi^{12}_\lambda(X_t) - 1)_{t\ge 0} : \lambda > 0\} \tag{6.13}$$
is tight in $\mathcal{C}_{\mathbb{R}}([0,\infty))$.
- **Step 3:** The finite-dimensional distributions of $\{((\lambda+1)\Psi^{12}_\lambda(X_t) - 1)_{t\ge 0} : \lambda > 0\}$ converge to 0 as $\lambda\to\infty$.

These steps imply that the object in (3.23) converges to 0 in distribution, which is (in the case of convergence to a constant) equivalent to convergence in probability.

Step 1: Start in equilibrium. Let $\widetilde{\mathcal{X}} = (\widetilde{X}_t)_{t\geq 0}$ with $\widetilde{X}_t = \overline{(\widetilde{U}_t, \widetilde{r}_t, \widetilde{\mu}_t)}$ be the tree-valued Fleming–Viot process started in equilibrium. Then, $\mathcal{X}$ and $\widetilde{\mathcal{X}}$ can be coupled such that for $\varepsilon > 0$

$$\langle \widetilde{\mu}_t^{\otimes\mathbb{N}}, \phi\rangle = \langle \mu_t^{\otimes\mathbb{N}}, \phi\rangle \tag{6.14}$$

for all $\phi : \mathbb{R}^{\binom{\mathbb{N}}{2}} \to \mathbb{R}$ which depends only on elements in $\underline{\underline{r}}$ with values at most t.

Recall the Moran model approximation. Observe that distances evolve with time of rate $2t$ and may change by resampling events by being reset to zero. The coupling arises in this model for every N by taking the same resampling events for $\mathcal{X}$ and $\widetilde{\mathcal{X}}$ which defines the two processes on a common probability space. For this coupling,

$$\begin{aligned}\sup_{\varepsilon\leq t\leq\tau} (\lambda+1)|\Psi_\lambda^{12}(X_t) - \Psi_\lambda^{12}(\widetilde{X}_t)| &= \sup_{\varepsilon\leq t\leq\tau} (\lambda+1)|\langle \mu_t^{\otimes\mathbb{N}} - \widetilde{\mu}_t^{\otimes\mathbb{N}}, \mathbb{1}_{\{r(u_1,u_2)>t\}} e^{-\lambda r(u_1,u_2)}\rangle| \\ &\leq \langle \mu_t^{\otimes\mathbb{N}}, \lambda e^{-\lambda\varepsilon}\rangle + \langle \widetilde{\mu}_t^{\otimes\mathbb{N}}, \lambda e^{-\lambda\varepsilon}\rangle = 2\lambda e^{-\lambda\varepsilon} \xrightarrow{\lambda\to\infty} 0.\end{aligned} \tag{6.15}$$

Taking now on this common probability space the limit $N \to \infty$ results in the coupled laws.

Hence, it suffices to prove the assertion when started in equilibrium, i.e. 1. holds for all assertions which concern properties which depend only on distances below a threshold and in particular all limiting properties close to the leaves.

Step 2: Tightness of $\{((\lambda+1)\Psi_\lambda^{12}(X_t) - 1)_{t\geq 0} : \lambda > 0\}$. This is clearly implied by Lemma 5.5 and the Kolmogorov–Chentsov criterion for tightness in $\mathcal{C}_\mathbb{R}([0,\infty))$.

Step 3: Convergence of finite-dimensional distributions to 0. This follows from Lemma 5.1.

6.5 Proof of Theorem 4

We proceed in several steps.

- **Step 0**: Warm up; computation of first two moments of $W_\lambda(t) - W_\lambda(s)$.
- **Step 1**: The family $(W_\lambda)_{\lambda>0}$ is tight in $\mathcal{C}_\mathbb{R}([0,\infty))$.
- **Step 2**: If $(W(t))_{t\geq 0}$ is realization of a limit point, then $(W(t))_{t\geq 0}$ and $(W(t)^2 - t)_{t\geq 0}$ are both martingales.

Throughout we let $(\mathcal{F}_t)_{t\geq 0}$ be the canonical filtration of the process $(\mathcal{X}_t)_{t\geq 0}$.

Step 0: Computation of first two moments of $W_\lambda(t) - W_\lambda(s)$. We start with some basic computations which we will need in the sequel. First, recall that $(\lambda+1)\Upsilon_\lambda^{12} = (\lambda+1)\Psi_\lambda^{12} - 1$ and by Lemma 5.8

$$\mathbf{E}[(\lambda+1)\Upsilon_\lambda^{12}(X_t)|\mathcal{F}_s] = e^{-\lambda(t-s)} \cdot (\lambda+1)\Upsilon_\lambda^{12}(X_s). \tag{6.16}$$

Then, by Fubini's theorem

$$\begin{aligned}\mathbf{E}[W_\lambda(t) - W_\lambda(s)|\mathcal{F}_s] &= \lambda \int_s^t \mathbf{E}[(\lambda+1)\Upsilon_\lambda^{12}(X_r)|\mathcal{F}_s]\, dr \\ &= \lambda \int_s^t e^{-\lambda(r-s)} \cdot (\lambda+1)\Upsilon_\lambda^{12}(X_s)\, dr \\ &= (1 - e^{-\lambda(t-s)}) \cdot (\lambda+1)\Upsilon_\lambda^{12}(X_s).\end{aligned} \tag{6.17}$$

We compute

$$\begin{aligned}
((\lambda+1)\Upsilon_\lambda^{12})^2 &= (\lambda+1)^2\Psi^{12,34} - 2(\lambda+1)\Psi_\lambda^{12} + 1\\
&= (\lambda+1)^2\Big(\Upsilon_\lambda^{12,34} + \frac{4}{3}\Upsilon_\lambda^{12,23} + \frac{2}{5}\Upsilon_\lambda^{12,12} + \frac{2(\lambda+6)}{(\lambda+2)(\lambda+5)}\Upsilon_\lambda^{12}\\
&\qquad + \frac{4\lambda^2+18\lambda+9}{(\lambda+1)(\lambda+3)(2\lambda+1)(2\lambda+3)}\Big) - 2(\lambda+1)\Upsilon_\lambda^{12} - 1\\
&= (\lambda+1)^2\Big(\Upsilon_\lambda^{12,34} + \frac{4}{3}\Upsilon_\lambda^{12,23} + \frac{2}{5}\Upsilon_\lambda^{12,12}\Big) - \frac{8(\lambda+1)}{(\lambda+2)(\lambda+5)}\Upsilon_\lambda^{12}\\
&\qquad + \frac{2\lambda^2}{(\lambda+3)(2\lambda+1)(2\lambda+3)},
\end{aligned} \tag{6.18}$$

which already implies that

$$\mathbf{E}[W_\lambda(t) - W_\lambda(s)|\mathcal{F}_s] \xrightarrow{\lambda\to\infty} 0 \quad \text{in } L^2, \tag{6.19}$$

since we started in equilibrium. Hence $\mathbf{E}[\Upsilon_\lambda^k(X_0)] = 0$ as in Lemma (5.18).

Next, we come to the second moment

$$\begin{aligned}
\mathbf{E}[(W_\lambda(t) - W_\lambda(s))^2|\mathcal{F}_s] &= \lambda^2\cdot\mathbf{E}\Big[\Big(\int_s^t (\lambda+1)^2\Upsilon_\lambda^{12}(r)\,dr\Big)^2\Big|\mathcal{F}_s\Big]\\
&= 2\lambda^2\cdot\int_s^t\int_{r_1}^t \mathbf{E}\big[(\lambda+1)\Upsilon_\lambda^{12}(X_{r_1})\mathbf{E}[(\lambda+1)\Upsilon_\lambda^{12}(X_{r_2})|\mathcal{F}_{r_1}]\big|\mathcal{F}_s\big]\,dr_2\,dr_1\\
&= 2\lambda^2\cdot\int_s^t\int_{r_1}^t \mathbf{E}\big[(\lambda+1)^2\Upsilon_\lambda^{12}(X_{r_1})e^{-(\lambda+1)(r_2-r_1)}\Upsilon_\lambda^{12}(X_{r_1})\big|\mathcal{F}_s\big]\,dr_2\,dr_1\\
&= 2\frac{\lambda^2}{\lambda+1}\int_s^t (1-e^{-(\lambda+1)(t-r_1)})\cdot\mathbf{E}[((\lambda+1)\Upsilon_\lambda^{12}(X_{r_1}))^2|\mathcal{F}_s]\,dr_1\\
&= t - s + A_\lambda,
\end{aligned} \tag{6.20}$$

with

$$\begin{aligned}
A_\lambda &= A_{\lambda,1} + A_{\lambda,2} + A_{\lambda,3},\\
A_{\lambda,1} &= \int_s^t \Big(\frac{4\lambda^4}{(\lambda+1)(\lambda+3)(2\lambda+1)(2\lambda+3)} - 1\Big)\,dr_1,\\
A_{\lambda,2} &= \frac{2\lambda^2(\lambda+1)}{2\lambda+6}\cdot\Big((1-e^{-(2\lambda+6)(t-s)})\Upsilon_\lambda^{12,34}(X_s)\\
&\qquad + \frac{4(2\lambda+6)}{3(2\lambda+3)}(1-e^{-(2\lambda+3)(t-s)})\Upsilon_\lambda^{12,23}(X_s)\\
&\qquad\qquad + \frac{2(2\lambda+6)}{5(2\lambda+2)}(1-e^{-(2\lambda+2)(t-s)})\Upsilon_\lambda^{12,12}(X_s)\\
&\qquad\qquad\qquad - \frac{8(2\lambda+6)}{\lambda^2(\lambda+2)(\lambda+5)}(1-e^{-(\lambda+1)(t-s)})\Upsilon_\lambda^{12}(X_s)\Big)\\
&= A_{\lambda,21} + A_{\lambda,22} + A_{\lambda,23},\\
A_{\lambda,3} &= 2\lambda^2\lambda+1\int_s^t e^{-(\lambda+1)(t-r_1)}\cdot\mathbf{E}[((\lambda+1)\Upsilon_\lambda^{12}(X_{r_1}))^2|\mathcal{F}_s]\,dr_1,
\end{aligned} \tag{6.21}$$

where

$$\begin{aligned}
A_{\lambda,21} &= \frac{\lambda^2(\lambda+1)}{\lambda+3}\Big(\Psi_\lambda^{12,34}(X_s) - \frac{4\lambda^2+18\lambda+9}{(\lambda+1)(\lambda+3)(2\lambda+1)(2\lambda+3)}\Big),\\
A_{\lambda,22} &= -\frac{2(\lambda+1)(\lambda^3+6\lambda^2+8\lambda+24)}{(\lambda+3)(2+\lambda)(5+\lambda)}\Upsilon_\lambda^{12}(X_s),
\end{aligned}$$

$$\begin{aligned}A_{\lambda,23} = -e^{-(2\lambda+6)(t-s)}\frac{2\lambda^2(\lambda+1)}{2\lambda+6}\Upsilon_\lambda^{12,34}(X_s) - \frac{8\lambda^2(\lambda+1)}{3(2\lambda+3)}e^{-(2\lambda+3)(t-s)}\Upsilon_\lambda^{12,23}(X_s)\\ - e^{-(2\lambda+2)(t-s)}\frac{4\lambda^2(\lambda+1)}{5(2\lambda+2)}\Upsilon_\lambda^{12,12}(X_s) + \frac{2(\lambda+1)}{(\lambda+2)(\lambda+5)}e^{-(\lambda+1)(t-s)}\Upsilon_\lambda^{12}(X_s).\end{aligned}$$

Since

$$\begin{aligned}A_{\lambda,1} &\xrightarrow{\lambda\to\infty} 0,\\ A_{\lambda,21}, A_{\lambda,22} &\xrightarrow{\lambda\to\infty} 0 \quad \text{in } L^2,\\ A_{\lambda,23}, A_{\lambda,3} &\xrightarrow{\lambda\to\infty} 0 \quad \text{in } L^1,\end{aligned} \tag{6.22}$$

we have

$$\mathbf{E}[(W_\lambda(t) - W_\lambda(s))^2|\mathcal{F}_s] \xrightarrow{\lambda\to\infty} t-s \quad \text{in } L^1. \tag{6.23}$$

Step 1: The family $(W_\lambda)_{\lambda>0}$ is tight in $\mathcal{C}_\mathbb{R}([0,\infty))$. Again, we use the Kolmogorov–Chentsov criterion. To this end we bound the fourth moments of the increments in W_λ:

$$\begin{aligned}&\mathbf{E}[(W_\lambda(t) - W_\lambda(s))^4]\\ &= \lambda^4\cdot\mathbf{E}\Big[\Big(\Upsilon_\lambda^{12}(X_t) - \Upsilon_\lambda^{12}(X_0) - \int_0^t(\lambda+1)\Upsilon_\lambda^{12}(X_s)ds - \Psi_\lambda^{12}(X_t) + \Psi_\lambda^{12}(X_0)\Big)^4\Big]\\ &\lesssim \lambda^4\Big(\mathbf{E}\Big[\Big(\Upsilon_\lambda^{12}(X_t) - \Upsilon_\lambda^{12}(X_0) - \int_0^t(\lambda+1)\Upsilon_\lambda^{12}(X_s)ds\Big)^4\Big]\\ &+ \mathbf{E}\big[(\Psi_\lambda^{12}(X_t) - \Psi_\lambda^{12}(X_0))^4\big]\Big)\end{aligned} \tag{6.24}$$

The second term is bounded by Ct^2 for some $C > 0$ which is independent of λ by Lemma 5.5. For the first term, we use the Burkholder–Davis–Gundy inequality and write (recall Lemma 5.8 and the quadratic variation of the semimartingale $\Psi_\lambda^{12}(\mathcal{X}) = (\Psi_\lambda^{12}(X_t))_{t\geq 0}$ from Remark 2.14):

$$\begin{aligned}&\lambda^4\cdot\mathbf{E}\Big[\Big(\Upsilon_\lambda^{12}(X_t) - \Upsilon_\lambda^{12}(X_0) + \int_0^t(\lambda+1)\Upsilon_\lambda^{12}(X_s)ds\Big)^4\Big]\\ &\quad\lesssim \lambda^4\mathbf{E}\big[[\Psi_\lambda^{12}(\mathcal{X})]_t^2\big]\\ &\quad= \lambda^4\int_0^t\int_0^s\mathbf{E}\big[(\Psi_\lambda^{12,23}(X_r) - \Psi_\lambda^{12,34}(X_r))\cdot\mathbf{E}[\Psi_\lambda^{12,23}(X_s) - \Psi_\lambda^{12,34}(X_s)|\mathcal{F}_r]\big]\,dr\,ds.\end{aligned} \tag{6.25}$$

We have to show that the integrand is of order $1/\lambda^4$, if X_0 is in equilibrium.

First, we compute the conditional expectation using Lemma 5.8.b using (5.22) and obtain

$$\begin{aligned}&\mathbf{E}[\Psi_\lambda^{12,23}(X_s) - \Psi_\lambda^{12,34}(X_s)|\mathcal{F}_r]\\ &\quad= \mathbf{E}\Big[\frac{1}{10}\Upsilon_\lambda^{12,12}(X_s) - \frac{1}{3}\Upsilon_\lambda^{12,23}(X_s) - \Upsilon_\lambda^{12,34}(X_s) - \frac{2}{(\lambda+2)(\lambda+5)}\Upsilon_\lambda^{12}(X_s)\Big|\mathcal{F}_r\Big]\\ &\qquad\qquad + \frac{\lambda^2}{(\lambda+1)(\lambda+3)(2\lambda+1)(2\lambda+3)}\\ &\quad= e^{-(2\lambda+1)(s-r)}\frac{1}{10}\Upsilon_\lambda^{12,12}(X_r) - e^{-(2\lambda+3)(s-r)}\frac{1}{3}\Upsilon_\lambda^{12,23}(X_r) - e^{-(2\lambda+6)(s-r)}\Upsilon_\lambda^{12,34}(X_r)\\ &\qquad - e^{-(\lambda+1)(s-r)}\frac{2}{(\lambda+2)(\lambda+5)}\Upsilon_\lambda^{12}(X_r) + \frac{\lambda^2}{(\lambda+1)(\lambda+3)(2\lambda+1)(2\lambda+3)}.\end{aligned} \tag{6.26}$$

Abbreviating $\Upsilon_\lambda^k := \Upsilon_\lambda^k(X_\infty)$, note that by (5.19) and the last display, the integrand in (6.25) is a linear combination of terms of the form $\mathbf{E}[(\Psi_\lambda^{12,23} - \Psi_\lambda^{12,34})(\Psi_\lambda^k - \mathbf{E}[\Psi_\lambda^k])]$ for $k \in \{12; 12, 12; 12, 23; 12, 34\}$. We compute all these terms:

$$\begin{aligned}
&\mathbf{E}\Big[(\Psi_\lambda^{12,23} - \Psi_\lambda^{12,34})\Big(\Psi_\lambda^{12} - \frac{1}{\lambda+1}\Big)\Big] \\
&\quad = \mathbf{E}[\Psi^{12,23,45} - \Psi^{12,34,56}] - \frac{1}{\lambda+1}\mathbf{E}[\Psi_\lambda^{12,23} - \Psi_\lambda^{12,34}] \\
&\quad = \frac{4\lambda^3(5\lambda^2 + 9\lambda - 10)}{(\lambda+1)^2(\lambda+3)(\lambda+5)(4\lambda^2 + 8\lambda + 3)(9\lambda^3 + 51\lambda^2 + 76\lambda + 20)} \\
&\quad = \mathcal{O}\Big(\frac{1}{\lambda^4}\Big),
\end{aligned} \tag{6.27}$$

$$\begin{aligned}
&\mathbf{E}\Big[(\Psi_\lambda^{12,23} - \Psi_\lambda^{12,34})\Big(\Psi_\lambda^{12,12} - \frac{1}{2\lambda+1}\Big)\Big] \\
&\quad = \mathbf{E}[\Psi_\lambda^{12,12,34,45} - \Psi^{12,12,34,56}] - \frac{1}{2\lambda+1}\mathbf{E}[\Psi_\lambda^{12,23} - \Psi_\lambda^{12,34}] \\
&\quad = \frac{2\lambda^3(1576\lambda^6 + \mathcal{O}(\lambda^5))}{3(\lambda+3)(2\lambda+1)^2(4\lambda+15)(2\lambda^2 + 5\lambda + 3)^2(96\lambda^5 + \mathcal{O}(\lambda^4))} \\
&\quad = \mathcal{O}\Big(\frac{1}{\lambda^4}\Big),
\end{aligned} \tag{6.28}$$

$$\begin{aligned}
&\mathbf{E}\Big[(\Psi_\lambda^{12,23} - \Psi_\lambda^{12,34})\Big(\Psi_\lambda^{12,23} - \frac{5\lambda+3}{(\lambda+1)(2\lambda+1)(2\lambda+3)}\Big)\Big] \\
&\quad = \mathbf{E}\Big[\Psi_\lambda^{12,23,45,56} - \Psi^{12,23,45,67}] - \frac{5\lambda+3}{(\lambda+1)(\lambda+3)(2\lambda+1)(2\lambda+3)}\mathbf{E}[\Psi_\lambda^{12,23} - \Psi_\lambda^{12,34}] \\
&\quad = \frac{2\lambda^2(683976\lambda^9 + \mathcal{O}(\lambda^8))}{9(\lambda+3)(2\lambda+1)^2(2\lambda^2 + 5\lambda + 3)^2(4\lambda^2 + 41\lambda + 105)(1152\lambda^7 + \mathcal{O}(\lambda^6))} \\
&\quad = \mathcal{O}\Big(\frac{1}{\lambda^5}\Big),
\end{aligned} \tag{6.29}$$

$$\begin{aligned}
&\mathbf{E}\Big[(\Psi_\lambda^{12,23} - \Psi_\lambda^{12,34})\Big(\Psi_\lambda^{12,34} - \frac{4\lambda^2 + 18\lambda + 9}{(\lambda+1)(\lambda+3)(2\lambda+1)(2\lambda+3)}\Big)\Big] \\
&\quad = \mathbf{E}[\Psi_\lambda^{12,23,45,67} - \Psi_\lambda^{12,34,56,78}] - \frac{4\lambda^2 + 18\lambda + 9}{(\lambda+1)(\lambda+3)(2\lambda+1)(2\lambda+3)}\mathbf{E}[\Psi_\lambda^{12,23} - \Psi_\lambda^{12,34}] \\
&\quad = \frac{4\lambda^2(20480\lambda^{11} + \mathcal{O}(\lambda^{10}))}{(\lambda+3)^2(\lambda+7)(2\lambda+1)^2(2\lambda^2 + 5\lambda + 3)^2(4608\lambda^9 + \mathcal{O}(\lambda^8))} \\
&\quad = \mathcal{O}\Big(\frac{1}{\lambda^5}\Big),
\end{aligned} \tag{6.30}$$

which shows that the integrand on the right hand side of (6.25) is $\mathcal{O}(1/\lambda^4)$.

Hence, we have shown that there is a constant $C > 0$ such that

$$\mathbf{E}[(W_\lambda(t) - W_\lambda(s))^4] \leq C(t-s)^2 \tag{6.31}$$

and we have shown tightness of $\{(W_\lambda(t))_{t\geq 0} : \lambda > 0\}$.

Step 2: If $(W_t)_{t\geq 0}$ is a limit point, $(W_t)_{t\geq 0}$ as well as $(W_t^2 - t)_{t\geq 0}$ are martingales. Let $\mathcal{W} = (W_t)_{t\geq 0}$ be a weak limit point of $\{(W_\lambda(t))_{t\geq 0} : \lambda > 0\}$. The claimed martingale properties follow by the same arguments as in Step 3 of the proof of Theorem 2.

7 Proof of Theorems 5 and 6

7.1 Proof of Theorem 5

To get a first idea, let us do a little computation. By Fubini's theorem, dominated convergence theorem and Lemma 5.8, we get

$$\begin{aligned}\mathbf{E}\Big[\int_0^T \lim_{\lambda\to\infty} \Psi_\lambda^{12}(X_t)dt\Big] &= \lim_{\lambda\to\infty} \int_0^T \mathbf{E}\big[\Psi_\lambda^{12}(X_t)\big]dt \\ &= \lim_{\lambda\to\infty} \frac{1}{\lambda+1}\int_0^T (1-\mathbf{E}\big[\Omega\Psi_\lambda^{12}(X_t)\big])\,dt \\ &= \lim_{\lambda\to\infty} \frac{1}{\lambda+1}\Big(T-\mathbf{E}[\Psi_\lambda^{12}(X_T)-\Psi_\lambda^{12}(0)]\Big) = 0,\end{aligned} \tag{7.1}$$

thus, since μ_t has no atom $\iff \lim_{\lambda\to\infty}\Psi_\lambda^{12}(X_t) = 0$,

$$\mathbf{P}(\mu_t \text{ has no atom for } \textit{almost} \text{ all } 0\le t\le T) = \mathbf{P}\Big(\int_0^T \mathbb{1}_{\{\lim_{\lambda\to\infty}\Psi_\lambda^{12}(X_t)>0\}}\,dt = 0\Big) = 1. \tag{7.2}$$

Our task is to remove the *almost* in the $\mathbf{P}(.)$ on the left hand side.

As in the proof of Theorem 3, it suffices to show the assertion if $X_0 \overset{d}{=} X_\infty$. Recall that $\Omega\Psi_\lambda^{12} = 1-(\lambda+1)\Psi_\lambda^{12}$ from Lemma 5.8. Hence, for all $\lambda > 0$, the process $(M_\lambda(t))_{t\ge 0}$ defined as

$$M_\lambda(t) := \Psi_\lambda^{12}(X_t) - \Psi_\lambda^{12}(X_0) - \int_0^t (1-(\lambda+1)\Psi_\lambda^{12}(X_s))\,ds, \tag{7.3}$$

is a continuous martingale with quadratic variation (recall Remark 2.14)

$$[M_\lambda]_t = \int_0^t \big(\Psi_\lambda^{12,23}(X_s) - \Psi_\lambda^{12,34}(X_s)\big)ds. \tag{7.4}$$

Using (5.22) and recalling from Lemma 5.8 that the Υ's are mean-zero martingales

$$\lim_{\lambda\to\infty}\mathbf{E}[M_\lambda(t)^2] = \lim_{\lambda\to\infty}\int_0^t \mathbf{E}[\Psi_\lambda^{12,23}(X_s) - \Psi_\lambda^{12,34}(X_s)]\,ds = 0. \tag{7.5}$$

This implies for all $\varepsilon > 0$ by Doob's maximal inequality:

$$\lim_{\lambda\to\infty}\mathbf{P}(\sup_{0\le t\le T}|M_\lambda(t)| > \varepsilon) = 0. \tag{7.6}$$

Then we can start calculating as follows. For all $\varepsilon > 0$, using again Fubini's theorem and then (5.23),

$$\begin{aligned}&\lim_{\lambda\to\infty}\mathbf{P}\Big(\sup_{0\le t\le T}\Big|\int_0^t (1-(\lambda+1)\Psi_\lambda^{12}(X_s))\,ds\Big| > \varepsilon\Big) \\ &\quad= \lim_{\lambda\to\infty}\mathbf{P}\Big(\sup_{0\le t\le T}\Big(\int_0^t \big(1-(\lambda+1)\Psi_\lambda^{12}(X_s)\big)\,ds\Big)^2 > \varepsilon^2\Big) \\ &\quad\le \lim_{\lambda\to\infty}\mathbf{P}\Big(\sup_{0\le t\le T}\int_0^t \big(1-(\lambda+1)\Psi_\lambda^{12}(X_s)\big)^2\,ds > \varepsilon^2\Big) \\ &\quad= \lim_{\lambda\to\infty}\mathbf{P}\Big(\int_0^T \big(1-(\lambda+1)\Psi_\lambda^{12}(X_s)\big)^2\,ds > \varepsilon^2\Big) \\ &\quad\le \lim_{\lambda\to\infty}\tfrac{1}{\varepsilon^2}\int_0^T \mathbf{E}\big[\big(1-(\lambda+1)\Psi_\lambda^{12}(X_s)\big)^2\big]\,ds \\ &\quad= 0.\end{aligned} \tag{7.7}$$

Hence, by (7.6) and (7.7), there is a subsequence $\lambda_n \uparrow \infty$ with

$$\sup_{0<t\leq T} |M_{\lambda_n}(t)| \xrightarrow{n\to\infty} 0, \tag{7.8}$$
$$\sup_{0<t\leq T} \Big| \int_0^t 1 - (\lambda_n + 1)\Psi^{12}_{\lambda_n}(X_s)\, ds \Big| \xrightarrow{n\to\infty} 0$$

almost surely. Recall that we can characterize the existence of atoms by the property whether we can draw two points at distance zero or not which we can in turn characterize by the $\lambda \to \infty$ limit of the sample Laplace transform. Combining (7.3) with (7.8) and with (7.2) (which allows to discard the $\Psi^{12}_{\lambda_n}(0)$) gives

$$\begin{aligned} &\mathbf{P}(\mu_t \text{ has no atoms for all } 0 < t \leq T) = \mathbf{P}(\lim_{n\to\infty} \sup_{0<t\leq T} \Psi^{12}_{\lambda_n}(X_t) = 0) \\ &\quad = \mathbf{P}\Big(\lim_{n\to\infty} \sup_{0<t\leq T} \Big(M_{\lambda_n}(t) + \int_0^t (1 - (\lambda_n + 1)\Psi^{12}_{\lambda_n}(X_s))\, ds \Big) = 0 \Big) = 1. \end{aligned} \tag{7.9}$$

7.2 Proof of Theorem 6

It turns out that the following simple criterion for existence of a mark function is useful.

Lemma 7.1 (Criterion for mark function)**.**
An mmm-space $\overline{(U, r, \mu)} \in \mathbb{U}_A$ *admits a mark function if there is a sequence* $\varepsilon_n \downarrow 0$ *with*

$$\lim_{n\to\infty} \mathbf{P}\big(\mathfrak{A}_1 = \mathfrak{A}_2 | r_U(\mathfrak{U}_1, \mathfrak{U}_2) < \varepsilon_n\big) = 1. \tag{7.10}$$

where $(\mathfrak{U}_1, \mathfrak{A}_1), (\mathfrak{U}_2, \mathfrak{A}_2)$ *are two independent pairs distributed according to* μ*. Equivalently,*

$$\frac{\langle \mu^{\otimes 2}, \mathbb{1}_{\{a_1=a_2\}} \mathbb{1}_{\{r(u_1,u_2)<\varepsilon_n\}}\rangle}{\langle \mu^{\otimes 2}, \mathbb{1}_{\{r(u_1,u_2)<\varepsilon_n\}}\rangle} \xrightarrow{n\to\infty} 1. \tag{7.11}$$

We proceed in three steps to prove Theorem 6.

- **Step 1**: Proof of Lemma 7.1.
- **Step 2**: An extension of Theorem 3.
- **Step 3**: Combination of Steps 1 and 2 gives Theorem 6.

Step 1: Proof of Lemma 7.1. Since μ is a probability measure on $U \times A$, we can write $\mu(du, da) = (\pi_U)_*\mu(du) \otimes K(u, da)$ for some probability kernel K from U to A. We have to show that $K(u, da)$ only has a single atom for $(\pi_U)_*\mu$-almost every u.

We proceed by contradiction and assume that $K(u, \cdot)$ is not concentrated on a single atom for a set $U' \subseteq U$ of positive $(\pi_U)_*\mu$-probability, i.e. $\mu(U' \times A) = \delta > 0$.

Then, for all sequences $\varepsilon_n \downarrow 0$

$$\limsup_{n\to\infty} \frac{\langle \mu^{\otimes 2}, \mathbb{1}_{\{a_1=a_2\}} \mathbb{1}_{\{u_1,u_2\in U', r(u_1,u_2)<\varepsilon_n\}}\rangle}{\langle \mu^{\otimes 2}, \mathbb{1}_{\{u_1,u_2\in U', r(u_1 u_2)<\varepsilon_n\}}\rangle} = 1 - \delta' < 1. \tag{7.12}$$

Applying this to the pairs $(\mathfrak{A}_1, \mathfrak{U}_1)$ and $(\mathfrak{A}_2, \mathfrak{U}_2)$ gives

$$\begin{aligned} &\limsup_{n\to\infty} [\mathbf{P}\big(\mathfrak{A}_1 = \mathfrak{A}_2 | r_U(\mathfrak{U}_1, \mathfrak{U}_2) < \varepsilon_n\big) \\ &\qquad = \limsup_{\varepsilon_n\to 0} \mathbf{P}\big(\mathfrak{A}_1 = \mathfrak{A}_2 | r_U(\mathfrak{U}_1, \mathfrak{U}_2) < \varepsilon_n, \mathfrak{U}_1, \mathfrak{U}_2 \in U'\big) \cdot \mathbf{P}(\mathfrak{U}_1, \mathfrak{U}_2 \in U') \\ &\qquad\quad + \mathbf{P}\big(\mathfrak{A}_1 = \mathfrak{A}_2 | r_U(\mathfrak{U}_1, \mathfrak{U}_2) < \varepsilon_n, \mathfrak{U}_1 \notin U_2 \vee \mathfrak{U}_2 \notin U'\big) \cdot \mathbf{P}(\mathfrak{U}_1 \in U' \vee \mathfrak{U}_2 \in U')] \\ &\qquad \leq (1 - \delta') \cdot \mathbf{P}(\mathfrak{U}_1, \mathfrak{U}_2 \in U') + \mathbf{P}(\mathfrak{U}_1 \notin U' \vee \mathfrak{U}_2 \notin U') < 1. \end{aligned} \tag{7.13}$$

Hence, (7.10) cannot hold if $\mathbf{P}(\mathfrak{U}_1, \mathfrak{U}_2 \in U') > 0$. This quantity however is by assumption bounded below by $\delta^2 > 0$ and we have shown Lemma 7.1.

Step 2: Extension of Theorem 3. We will show the following for

$$\widehat{\Psi}^{12}_\lambda(\overline{(U,r,\mu)}) := \int \mu^{\otimes 2}(du_1, du_2, da_1, da_2) \mathbb{1}_{\{a_1 = a_2\}} e^{-\lambda r(u_1,u_2)}, \tag{7.14}$$

from (2.7): For all $T < \infty$ and $\varepsilon > 0$,

$$\lim_{\lambda \to \infty} \mathbf{P}\left(\sup_{\varepsilon \le t \le T} |(\lambda+1)\widehat{\Psi}^{12}_\lambda(X_t) - 1| > \varepsilon \right) = 0. \tag{7.15}$$

In order to see this, it suffices – analogously to the proof of Theorem 3 – to consider $\alpha = 0$ and to start in equilibrium $X_0 \stackrel{d}{=} X_\infty$. First, we assume that $\beta(\cdot,\cdot)$ is non-atomic, i.e. (5.2) from Section 5 holds. In this case, we proceed as in Steps 2 and 3 from Section 6.4. These steps rely on Lemmata 5.1 and 5.5, and we can read off from the second assertions from these Lemmata that (7.15) holds. Second, consider the general case, i.e. $\beta(\cdot,\cdot)$ is not necessarily non-atomic. It is straight-forward to construct a coupling $(X_t, \check{X}_t)_{t\ge 0}$ such that $(X_t)_{t\ge 0}$ and $(\check{X}_t)_{t\ge 0}$ use the same resampling and mutation events, where mutant types in $(X_t)_{t\ge 0}$ are chosen according to $\beta(\cdot,\cdot)$, but mutant types in $(\check{X}_t)_{t\ge 0}$ are chosen (at the same rate) according to some non-atomic $\check{\beta}(\cdot,\cdot)$. If $X_0 = \check{X}_0$, it is clear that mutant types in $(\check{X}_t)_{t\ge 0}$ lead to new types in any case and thus, the inequality

$$\widehat{\Psi}^{12}(\check{X}_t) \le \widehat{\Psi}^{12}(X_t) \le \Psi^{12}(X_t) = \Psi^{12}(\check{X}_t) \tag{7.16}$$

holds for all $t \ge 0$, almost surely. Recall that we have already shown in Theorem 3 that (7.15) holds if $\widehat{\Psi}^{12}$ is replaced by Ψ^{12}, and since $\check{\beta}(\cdot,\cdot)$ is non-atomic, it also holds for $(\check{X}_t)_{t\ge 0}$ by our arguments above. Hence, by (7.16), it also holds for $\widehat{\Psi}^{12}(X_t)$, i.e. we have shown (7.15).

Step 3: Combination of Steps 1 and 2 gives Theorem 6. Fix $0 < \delta < T < \infty$. It suffices to show that $\mathcal{X}_t \in \mathbb{U}_A^{\text{mark}}$ for all $\delta \le t \le T$. Using Theorem 3 and Step 2 above, take a sequence $\varepsilon_n \downarrow 0$ and set $\lambda_n := 1/\varepsilon_n$ such that

$$\begin{aligned} &\mathbf{P}(\lim_{n\to\infty} \lambda_n \langle \mu_t^{\otimes 2}, e^{-\lambda_n r_{12}} \rangle = 1 \text{ for all } \delta \le t \le T) = 1, \\ &\mathbf{P}(\lim_{n\to\infty} \lambda_n \langle \mu_t^{\otimes 2}, \mathbb{1}_{\{a_1=a_2\}} e^{-\lambda_n r_{12}} \rangle = 1 \text{ for all } \delta \le t \le T) = 1. \end{aligned} \tag{7.17}$$

We use Lemma 7.1 and the Tauberian result from Lemma 3.4 with its obvious extension to $\widehat{\Psi}^{12}_\lambda$ to write:

$$\begin{aligned} \mathbf{P}(\mathcal{X}_t = &\overline{(U_t, r_t, \mu_t)} \in \mathbb{U}_A^{\text{mark}} \text{ for all } \delta \le t \le T) \\ &\ge \mathbf{P}\Big(\lim_{n\to\infty} \frac{\langle \mu_t^{\otimes 2}, \mathbb{1}_{\{a_1=a_2\}} \mathbb{1}_{\{r(u_1,u_2)<\varepsilon_n\}} \rangle}{\langle \mu_t^{\otimes 2}, \mathbb{1}_{\{r(u_1,u_2)<\varepsilon_n\}} \rangle} = 1 \text{ for all } \delta \le t \le T \Big) \\ &\ge \mathbf{P}\Big(\lim_{n\to\infty} \lambda_n \langle \mu_t^{\otimes 2}, \mathbb{1}_{\{a_1=a_2\}} \mathbb{1}_{\{r(u_1,u_2)<\varepsilon_n\}} \rangle = 1 \\ &\qquad\qquad \text{and } \lim_{n\to\infty} \lambda_n \langle \mu_t^{\otimes 2}, \mathbb{1}_{\{r(u_1,u_2)<\varepsilon_n\}} \rangle = 1 \text{ for all } \delta \le t \le T \Big) \\ &= \mathbf{P}\Big(\lim_{n\to\infty} \lambda_n \langle \mu_t^{\otimes 2}, \mathbb{1}_{\{a_1=a_2\}} e^{-\lambda r(u_1,u_2)} \rangle = 1 \\ &\qquad\qquad \text{and } \lim_{n\to\infty} \lambda_n \langle \mu_t^{\otimes 2}, e^{-\lambda r(u_1,u_2)} \rangle = 1 \text{ for all } \delta \le t \le T \Big) \\ &= 1 \end{aligned} \tag{7.18}$$

by (7.17). This concludes the proof of Theorem 6.
